## PREFACE TO THE PRESENT EDITION.

---

THE arrangement and classification followed in previous editions have been continued.

Those portions of the work dealing with chemical physics and with mineral chemistry have been extended in the light of discoveries announced since the appearance of the second edition.

The orthography of certain words, as chlorin, chlorids, has been modified in accordance with the views expressed in the report of the committee of the Chemical Section of the American Association for the Advancement of Science (see Appendix A).

That portion of the work treating of the chemistry of the carbon compounds has been much extended and in great part rewritten. The prominence given to this branch of the subject the author believes to be justified, notwithstanding its intricacy and the consequent difficulty of teaching it satisfactorily to medical students, by reason of the intimate connection of organic chemistry with physiology and with modern pharmacy, and the rapidly increasing use of complex organic products, natural and synthetic, as medicines.

R. A. W.

NEW YORK, September 21st, 1890.

## PREFACE TO THE FIRST EDITION.

---

IN venturing to add another to the already long list of chemical text-books, the author trusts that he may find some apology in this, that the work is intended solely for the use of a class of students whose needs in the study of this science are peculiar.

While the main foundations of chemical science, the philosophy of chemistry, must be taught to and studied by all classes of students alike, the subsequent development of the study in its details must be moulded to suit the purposes to which the student will subsequently put his knowledge. And particularly in the case of medical students, in our present defective methods of medical teaching, should the subject be confined as closely as may be to the general truths of chemistry and its applications to medical science.

In the preparation of this Manual the author has striven to produce a work which should contain as much as possible of those portions of special chemistry which are of direct interest to the medical practitioner, and at the same time to exclude so far as possible, without detriment to a proper understanding of the subject, those portions which are of purely technological interest. The descriptions of processes of manufacture are therefore made very brief, while chemical physiology and the chemistry of hygiene, therapeutics, and toxicology have been dwelt upon.

The work has been divided into three parts. In the first part the principles of chemical science are treated of, as well as so much of chemical physics as is absolutely requisite to a proper understanding of that which follows. A more extended study of physics is purposely avoided, that subject being, in the opinion of the author, rather within the domain of physiology than of chemistry.

The second part treats of special chemistry, and in this certain departures from the methods usually followed in chemical text-

books are to be noted. The elements are classed, not in metals and metalloids, a classification as arbitrary as unscientific, but into classes and groups according to their *chemical* characters.

In the text the formula of a substance is used in most instances in place of its name, *after it has been described*, with a view to giving the student that familiarity with the notation which can only be obtained by continued use.

In the third part those operations and manipulations which will be of utility to the student and physician are briefly described: not with the expectation that these directions can take the place of actual experience in the laboratory, but merely as an outline sketch in aid thereto.

Although the Manual puts forth no claim as a work upon analytical chemistry, we have endeavored to bring that branch of the subject rather into the foreground so far as it is applicable to medical chemistry. The qualitative characters of each element are given under the appropriate heading, and in the third part, a systematic scheme for the examination of urinary calculi is given. Quantitative methods of interest to the physician are also described in their appropriate places. In this connection the author would not be understood as saying that the methods recommended are in all instances the best known, but simply that they are the best adapted to the limited facilities of the physician.

The author would have preferred to omit all mention of Troy and Apothecaries' weight, but in deference to the opinions of those venerable practitioners who have survived their student days by a half-century, those weights have been introduced in brackets after the metric, as the value of degrees Fahrenheit have been made to follow those Centigrade.

# THE MEDICAL STUDENT'S MANUAL OF CHEMISTRY.

---

## PART I.

### INTRODUCTION.

THE simplest definition of chemistry is a modification of that given by Webster : **That branch of science which treats of the composition of substances, their changes in composition, and the laws governing such changes.**

If a bar of soft iron be heated sufficiently it becomes luminous ; if caused to vibrate it emits sound ; if introduced within a coil of wire through which a galvanic current is passing, it becomes magnetic and attracts other iron brought near it. Under all these circumstances the iron is still iron, and so soon as the heat, vibration, or galvanic current ceases, it will be found with its original characters unchanged ; it has suffered no change in composition. If now the iron be heated in an atmosphere of oxygen gas, it burns, and is converted into a substance which, although it contains iron, has neither the appearance nor the properties of that metal. The iron and a part of the oxygen have disappeared, and have been converted into a new substance, differing from either ; there has been change in composition, there has been chemical action. Changes wrought in matter by physical forces, such as light, heat, and electricity, are temporary, and last only so long as the force is active ; except in the case of changes in the state of aggregation, as when a substance is pulverized or fashioned into given shape. Changes in chemical composition are permanent, lasting until some other change is brought about by another manifestation of chemical action.

However distinct chemical may thus be from physical forces, it is none the less united with them in that grand correlation whose

existence was first announced by Grove, in 1842. As, from chemical action, manifestations of every variety of physical force may be obtained : light, heat, and mechanical force from the oxidation of carbon ; and electrical force from the action of zinc upon sulphuric acid—so does chemical action have its origin, in many instances, in the physical forces. Luminous rays bring about the chemical decomposition of the salts of silver, and the chemical union of chlorine and hydrogen ; by electrical action a decomposition of many compounds into their constituents is instituted, while instances are abundant of reactions, combinations, and decompositions which require a certain elevation of temperature for their production. While, therefore, chemistry in the strictest sense of the term, deals only with those actions which are attended by a change of composition in the material acted upon, yet chemical actions are so frequently, nay universally, affected by existing physical conditions, that the chemist is obliged to give his attention to the science of physics, in so far, at least, as it has a bearing upon chemical reactions, to *chemical physics*—a branch of the subject which has afforded very important evidence in support of theoretical views originating from purely chemical reactions.

### General Properties of Matter.

**Indestructibility.**—The result of chemical action is change in the composition of the substance acted upon, a change accompanied by corresponding alterations in its properties. Although we may cause matter to assume a variety of different forms, and render it, for the time being, invisible, yet in none of these changes is there the smallest particle of matter destroyed. When carbon is burned in an atmosphere of oxygen, it disappears, and, so far as we can learn by the senses of sight or touch, is lost ; but the result of the burning is an invisible gas, whose weight is equal to that of the carbon which has disappeared, plus the weight of the oxygen required to burn it.

**Impenetrability.**—Although one mass of matter may penetrate another, as when a nail is driven into wood, or when salt is dissolved in water ; the ultimate particles of which matter is composed cannot penetrate each other, and, in cases like those above cited, the particles of the softer substance are forced aside, or the particles of one substance occupy spaces between the particles of the other. Such spaces exist between the ultimate particles of even the densest substances.

**Weight.**—All bodies attract each other with a force which is in direct proportion to the amount of matter which they contain. The force of this attraction, exerted upon surrounding bodies by

the earth, becomes sensible as weight, when the motion of the attracted body toward the centre of gravity of the earth is prevented.

In chemical operations we have to deal with three kinds of weight: **absolute**, **apparent**, and **specific**.

The **Absolute Weight** of a body is its weight in vacuo. It is determined by placing the entire weighing apparatus under the receiver of an air-pump.

The **Apparent Weight**, or **Relative Weight**, of a body is that which we usually determine with our balances, and is, if the volume of the body weighed be greater than that of the counterpoising weights, less than its true weight. Every substance in a liquid or gaseous medium suffers a loss of apparent weight equal to that of the volume of the medium so displaced. For this reason the apparent weight of some substances may be a minus quantity. Thus, if the air contained in a vessel suspended from one arm of a poised balance be replaced by hydrogen, that arm of the balance to which the vessel is attached will rise, indicating a diminution in weight. (See Weighing; Part III.)

The **Specific Weight**, or **Specific Gravity**, of a substance is the weight of a given volume of that substance, as compared with the weight of an equal bulk of some substance, accepted as a standard of comparison, under like conditions of temperature and pressure. The sp. gr. of solids and liquids are referred to water; those of gases to air or to hydrogen.\* Thus the sp. gr. of sulphuric acid being 1.8, it is, volume for volume, one and eight-tenths times as heavy as water. As, by reason of their different rates of expansion by heat, solids and liquids do not have the same sp. gr. at all temperatures, that at which the observation is made should always be noted, or some standard temperature adopted. The standard temperature adopted by some continental writers and in the U. S. P. is 15° (59° F.). Other standard temperatures are 4° (39.2° F.), the point of greatest density of water, used by most continental writers, and 15.6° (60° F.), used in Great Britain and to some extent in this country.

The determination of the specific weight of a substance is frequently of great service. Sometimes it affords a rapid means of distinguishing between two substances similar in appearance; sometimes in determining the quantity of an ingredient in a mixture of two liquids, as alcohol and water; and frequently in determining approximately the quantity of solid matter in solution in a liquid. It is the last object which we have in view in determining the sp. gr. of the urine.

\* As the sp. gr. of pure air (hydrogen = 1) is 14.42, the sp. gr. in terms of air = 14.42 = sp. gr. in terms of hydrogen. Thus, the sp. gr. of hydrochloric acid gas (A = 1) is 1.359. Its sp. gr. (H = 1) is therefore  $1.359 \times 14.42 = 36.31$ .

An aqueous solution of a solid heavier than water has a higher sp. gr. than pure water, the variation in sp. gr. following a regular but different rate with each solid. In a simple solution—one of common salt in water, for instance—the proportion of solid in solution can be determined from the sp. gr. In complex solutions, such as the urine, the sp. gr. does not indicate the proportion of solid in solution with accuracy. In the absence of sugar and albumen, a determination of the sp. gr. of urine affords an indication of the amount of solids sufficiently accurate for usual clinical purposes. Moreover, as urea is much in excess over other urinary solids, the oscillations in the sp. gr. of the urine, if

the quantity passed in twenty-four hours be considered, and in the absence of albumen and sugar, indicate the variations in the elimination of urea, and consequently the activity of disassimilation of nitrogenous material.

To determine the sp. gr. of substances, different methods are adopted, according as the substance is in the solid, liquid, or gaseous state; is in mass or in powder; or is soluble or insoluble in water.

FIG. 1.

**SOLIDS.**—*The substance is heavier than water, insoluble in that liquid, and not in powder.*—It is attached by a fine silk fibre or platinum wire to a hook arranged on one arm of the balance, and weighed. A beaker full of pure water is then so placed that the body is immersed in it (Fig. 1), and a second weighing made. By dividing the weight in air by the loss in water, the sp. gr. (water = 1.00) is obtained. Example :

A piece of lead weighs in air.....	82.0
A piece of lead weighs in water.....	74.9
Loss in water.....	7.1

$$\frac{82.0}{7.1} = 11.55 = \text{sp. gr. of lead.}$$

*The substance is in powder, insoluble in water.*—The specific gravity bottle (Fig. 3), filled with water, and the powder, previously weighed and in a separate vessel, are weighed together. The water is poured out of the bottle, into which the powder is introduced, with enough water to fill the bottle completely. The weight of the bottle and its contents is now determined. The weight of the powder alone, divided by the loss between the first and second weighings, is the specific gravity. Example :

Weight of iron filings used.....	6.562
Weight of iron filings and sp. gr. bottle filled with water	148.327
Weight of sp. gr. bottle containing iron filings and filled with water.....	147.470

Water displaced by iron..... 0.857

6.562

0.857 = 7.65 = sp. gr. of iron.

*The substance is lighter than water.*—A sufficient bulk of some heavy substance, whose sp. gr. is known, is attached to it and the same method followed, the loss of weight of the heavy substance being subtracted from the total loss. Example :

A fragment of wood weighs .....	4.3946
A fragment of lead weighs .....	10.6193

Wood with lead attached weighs in air.....	15.0139
Wood with lead attached weighs in water.....	5.9295

Loss of weight of combination.....	9.0844
Loss of weight of lead in water (determined as above)	0.7903

Loss of weight of wood..... 8.2941

$\frac{4.3946}{8.2941} = 0.529 = \text{sp. gr. of wood.}$

*The substance is soluble in or decomposable by water.*—Its specific gravity, referred to some liquid not capable of acting on it, is determined, using that liquid as water is used in the case of insoluble substances. The sp. gr. so obtained, multiplied by that of the liquid used, is the sp. gr. sought. Example :

A piece of potassium weighs.....	2.576
A sp. gr. bottle full of naphtha, sp. gr. 0.758, weighs	22.784

	25.360
The bottle with potassium and naphtha weighs...	23.103

Loss..... 2.257

$\frac{2.576}{2.257} = 1.141 \times 0.758 = 0.865 = \text{sp. gr. of potassium.}$

**LIQUIDS.**—The sp. gr. of liquids is determined by the specific gravity balance, by the specific gravity bottle, sometimes called picnometer, or by the spindle or hydrometer.

*By the balance.*—The liquid, previously brought to the proper temperature, is placed in the cylinder *a* (Fig. 2), and the plunger immersed in it, and attached to the arm of the balance. The weights are now adjusted, beginning with the largest, until the balance is in equilibrium. The sp. gr. indicated by the balance in Fig. 2 is 1.98.

*By the bottle.*—An ordinary analytical balance is used. A bottle of thin glass (Fig. 3) is so made as to contain a given volume of water, say 100 c.c., at 15° C., and its weight is determined once for all. To use the pycnometer, it is filled with the liquid to be examined and weighed. The weight obtained, minus that of the bottle, is the sp. gr. sought, if the bottle contain 1000 c.c.: 1-10 if 100 c.c., etc. Example: Having a bottle whose weight is 35.35, and which contains 100 c.c.; filled with urine it weighs 137.91, the sp. gr. of the urine is  $137.91 - 35.35 = 102.56 \times 10 = 1025.6$ —Water = 1000.

FIG. 2.

*By the spindle.*—The method by the hydrometer is based upon the fact that a solid will sink in a liquid, whose sp. gr. is greater than its own, until it has displaced a volume of the liquid whose weight is equal to its own; and all forms of hydrometers are simply contrivances to measure the volume of liquid which they displace when immersed. The hydrometer most used by physicians is the urinometer (Fig. 4). It should not be chosen too small, as the larger the bulb, and the thinner and longer the stem, the more accurate are its indications. It should be tested by immersion in liquids of known sp. gr., and the error at different points of the scale should be noted on the box. The most convenient method of using the instrument is as follows: The cylinder, which should have a foot and rim, but no pouring lip,

is filled to within an inch of the top; the spindle is then floated and the cylinder completely filled with the liquid under examination (Fig. 4). The reading is then taken at the highest point *a*, where the surface of the liquid comes in contact with the spindle.\*

In all determinations of sp. gr. the liquid examined should have the temperature for which the instrument is graduated, as all liquids expand with heat and contract when cooled, and con-

FIG. 3.

FIG. 4.

sequently the result obtained will be too low if the urine or other liquid be at a temperature above that at which the instrument is intended to be used, and too high if below that temperature. An accurate correction may be made for temperature in simple solutions. In a complex fluid like the urine, however, this can only be done roughly by allowing 1 of sp. gr. for each  $3^{\circ}$  C. ( $5^{\circ}$ .4 Fahr.) of variation in temperature.

\*The advantages of the method described over that usually followed are: Greater facility in reading, less liability to error, the possibility of taking the reading in opaque liquids, and the fact that readings are made upward, not downward.

**GASES AND VAPORS.**—The specific gravities of gases and vapors are of great importance in theoretical chemistry, as from them we can determine molecular weights, in obedience to the law of Avogadro (p. 33).

*Gases.*—The specific gravities of gases are obtained as follows: A glass flask of about 300 c.c. capacity, having a neck 20 centimetres long and 6 millimetres in diameter, and fitted with a glass stopcock, is filled with mercury; reversed over mercury; and filled with the gas to just below the stopcock. The stopcock is now closed; the temperature,  $t$ ; the barometric pressure,  $H$ ; and the height of the mercurial column in the neck above that in the trough,  $h$ , are determined, and the flask weighed. Let  $P$  be the weight found, and  $V$  the capacity of the flask, determined once for all, then

$$\frac{V(H-h)}{760(1+0.00366t)} - V_0 = \text{the volume of the gas at } 0^\circ \text{ and 760 mm.}$$

The flask is then brought under the receiver of an air pump, the glass stopcock being open, and the air alternately exhausted and allowed to enter until the gas in the flask is replaced by air. The temperature  $t$ , the barometric pressure  $H$ , and the weight of the flask filled with air  $P'$ , are now determined. From these results the weight,  $K$ , of the gas occupying the volume  $V_0$  is obtained by the formula:

$$K = P - P' + \frac{VH}{760(1+0.00366t)} \times 0.001293$$

The sp. gr. referred to air is found by the formula:

$$\frac{K}{V_0 \times 0.001293}$$

and that referred to hydrogen by the formula:

$$\frac{K}{V_0 \times 0.001293 \times 0.06927}$$

*Vapors.*—The specific gravity of vapors is best determined by Meyer's method, as follows: A small, light glass vessel (Fig. 5) is filled completely with the solid or liquid whose vapor density is to be determined and weighed: from this weight that of the vessel is subtracted; the difference being the weight of the substance  $P$ . The small vessel and contents are now introduced into the large branch of the apparatus (Fig. 6), whose weight is then determined. The apparatus is now filled with mercury, the capillary opening at the top of the larger branch is closed by the blow-pipe, and the whole again weighed. The apparatus is suspended by a

FIG. 5.

metallic wire near the bottom of a long tube closed at the bottom, and containing about 50 c.c. of some liquid whose boiling-point is constant and higher than that of the substance experimented on. When the liquid has been heated to active

boiling, and the mercury ceases to escape from the small tube, the barometric pressure and the temperature of the air are observed. After the apparatus is cooled, the tube (Fig. 6), with its contents is weighed, and the difference in the level of mercury which existed in the two branches during the heating determined by breaking the capillary point, tilting the apparatus until the smaller branch is completely filled, marking the level of mercury in the larger branch, and afterward measuring the distance from that point to the opening.

By the above process the following factors are determined :

$P$ =weight of substance ;

$T$ =boiling-point of external liquid ;

$t$ =temperature of air ;

$H$ =barometric pressure reduced to  $0^\circ$  ;

$h$ =difference in level of mercury in two branches of tube ;

$h'$ =tension of vapor of mercury at  $T$  ;

$a$ =weight of mercury used ;

$q$ =weight of mercury required to fill the tube Fig. 5 ;

$r$ =weight of mercury remaining in the apparatus after heating.

From these the specific gravity, air = 1, is obtained by the equation :

$$D = \frac{P \cdot 760 (1 + 0.00367 T) 13.59}{(H - h - h') \cdot 0.0012932 [(a + q) \cdot 1 + 0.0000303 (T - t)] - r \cdot 1 + 0.00018 (T - t)} [1 + 0.00018 t]$$

The sp. gr. in terms of air=1 may be reduced to sp. gr. referred to hydrogen=2, by dividing by 0.06927.

**States of Matter.**—Matter exists in one of three states : solid, liquid, and gaseous. In the solid form, the particles of matter are comparatively close together, and are separated with more difficulty than are those of liquid or gaseous matter ; or in other words the cohesion of solid matter is greater than that of the other two forms. In the liquid, the particles are less firmly bound together, and are capable of freer motion about one another. In the gas, the mutual attraction of the particles disappears entirely, and their distance from each other depends upon the pressure to which the gas is subjected.

The term **fluid** applies to both liquids and gases, the former being designated as **incompressible**, from the very slight degree to which their volume can be reduced by pressure. The gases are designated as **compressible fluids**, from the fact that their volume can be reduced by pressure, to an extent limited only by their passage into the liquid form.

It is highly probable that all substances, which are not decomposed when heated, are capable of existing in the three forms of solid, liquid, and gas. There are, however, some substances which are only known in two forms—as alcohol : or in a single

form—as carbon; probably because we are as yet unable to produce artificially a temperature sufficiently low to solidify the one, or sufficiently high to liquefy or volatilize the other.

A vapor is an *aëriform* fluid into which a substance, solid or liquid at the ordinary temperature, is converted by elevation of temperature, or by diminution of pressure. Since the liquefaction of the so-called permanent gases, the distinction between gases and vapors is only one of degree and of convenience. A liquid is said to be **volatile** when, like ether, it is readily converted into vapor. It is said to be **fixed** if, like olive oil, it does not yield a vapor when heated. Certain solids are directly volatile, like camphor, passing from the condition of solid to that of vapor without liquefaction.

FIG. 6.

**Divisibility.**—All substances are capable of being separated, with greater or less facility, by mechanical means into minute particles. With suitable apparatus, gold may be divided into fragments, visible by the aid of the microscope, whose weight would be  $\frac{1}{10000000000}$  of a grain; and it is probable that when a solid is dissolved in a liquid a still greater subdivision is attained.

Although we have no direct experimental evidence of the existence of a limit to this divisibility, we are warranted in believing that matter is not infinitely divisible. A strong argument in favor of this view being that, after physical subdivision has reached the limit of its power with regard to compound substances, these may be further divided into dissimilar bodies by chemical means.

The limit of mechanical subdivision is the **molecule** of the physicist, the smallest quantity of matter with which he has to deal, the smallest quantity that is capable of free existence.

### Physical Characters of Chemical Interest.

**Crystallization.**—Solid substances exist in two forms, **amorphous** and **crystalline**. In the former they assume no definite shape; they conduct heat equally well in all directions; they break irregularly; and, if transparent, allow light to pass through them equally well in all directions. A solid in the crystalline form has a definite geometrical shape; conducts heat more readily in some directions than in others; when broken, separates in certain directions, called **planes of cleavage**, more readily than in others; and modifies the course of luminous rays passing through

it differently when they pass in certain directions than when they pass in others.

**Crystals** are formed in one of four ways: 1.) An amorphous substance, by slow and gradual modification, may assume the crystalline form; as vitreous arsenic trioxid (*q. c.*) passes to the crystalline variety. 2.) A fused solid, on cooling, crystallizes; as bismuth. 3.) When a solid is sublimed it is usually condensed

FIG. 7.

in the form of crystals. Such is the case with arsenic trioxid. 4.) The usual method of obtaining crystals is by the evaporation of a solution of the substance. If the evaporation be slow and the solution at rest, the crystals are large and well-defined. If the crystals separate by the sudden cooling of a hot solution, especially if it be agitated during the cooling, they are small.

Most crystals may be divided by imaginary planes into equal,

FIG. 8.

symmetrical halves. Such planes are called **planes of symmetry**. Thus in the crystals in Fig. 7 the planes *ab ab*, *ac ac*, and *bc bc* are planes of symmetry.

When a plane of symmetry contains two or more equivalent linear directions passing through the centre, it is called the **principal plane of symmetry**; as in Fig. 8 the plane *ab ab*, containing the equal linear directions *aa* and *bb*.

Any normal erected upon a plane of symmetry, and prolonged in both directions until it meets opposite parts of the exterior of the crystal, at equal distances from the plane, is called an **axis of symmetry**.

The axis normal to the principal plane is the **principal axis**. Thus in Fig. 8, *aa*, *bb*, and *cc* are axes of symmetry, and *cc* is the principal axis.

Upon the relations of these imaginary planes and axes a classification of all crystalline forms into six systems has been based.

**I. The Cubic, Regular, or Monometric System.**—The crystals of this system have three equal axes, *aa*, *bb*, *cc*, Fig. 7, crossing each other at right angles. The simple forms are the cube; and

FIG. 9.

its derivatives, the octahedron, tetrahedron, and rhombic dodecahedron. The crystals of this system expand equally in all directions when heated, and are not doubly refracting.

**II. The Right Square Prismatic, Pyramidal, Quadratic, Tetragonal, or Dimetric System** contains those crystals having three axes placed at right angles to each other—two as *aa* and *bb*, Fig. 8, being equal to each other and the third, *cc*, either longer or shorter. The simple forms are the right square prism and the right square based octahedron. The crystals of this system expand equally only in two directions when heated. They refract light doubly in all directions except through one axis of single refraction.

**III. The Rhombohedral or Hexagonal System** includes crystals having four axes, three of which *aa*, *aa*, *aa*, Fig. 9, are of

equal length and cross each other at  $60^\circ$  in the same plane; to which plane the fourth axis,  $cc$ , longer or shorter than the others, is at right angles. The simple forms are the regular six-sided prism, the regular dodecahedron, the rhombohedron, and the scalenohedron. These crystals expand equally in two directions when heated, and refract light singly through the principal axis, but in other directions refract it doubly.

IV. **The Rhombic, Right Prismatic, or Trimetric System.**—The axes of crystals of this system are three in number, all at right angles to each other, and all of unequal length. Fig. 8 represents crystals of this system, supposing  $aa$ ,  $bb$ , and  $cc$  to be unequal to each other. The simple forms are the right rhombic octahedron, the right rhombic prism, the right rectangular octahedron, and the right rectangular prism. The crystals of this

FIG. 10.

system, like those of the two following, have no true principal plane or axis.

V. **The Oblique, Monosymmetric, or Monoclinic System.**—The crystals of this system have three axes, two of which,  $aa$ , and  $cc$ , Fig. 10, are at right angles; the third,  $bb$ , is perpendicular to one and oblique to the other. They may be equal or all unequal in length. The simple forms are the oblique rectangular and oblique rhombic prism and octahedron.

VI. **The Doubly Oblique, Asymmetric, Triclinic, or Anorthic System** contains crystals having three axes of unequal length, crossing each other at angles not right angles; Fig. 10,  $aa$ ,  $bb$ , and  $cc$  being unequal and the angles between them other than  $90^\circ$ .

The crystals of the fourth, fifth, and sixth systems, when heated, expand equally in the directions of their three axes. They refract light doubly except in two axes.

**Secondary Forms.**—The crystals occurring in nature or produced artificially have some one of the forms mentioned above, or some modification of those forms. These modifications, or

**secondary forms**, may be produced by symmetrically removing the angles or edges, or both angles and edges, of the primary forms. Thus, by progressively removing the angles of the cube, the secondary forms shown in Fig. 11 are produced.

It sometimes happens in the formation of a derivative form that alternate faces are excessively developed, producing at length entire obliteration of the others, as shown in Fig. 12. Such crystals are said to be **hemihedral**. They can be developed only in a system having a principal axis.

FIG. 11.

**Isomorphism.**—In many instances two or more substances crystallize in forms identical with each other, and, in most cases, such substances resemble each other in their chemical constitution. They are said to be **isomorphous**. This identity of crystalline form does not depend so much upon the nature of the elements themselves, as upon the structure of the molecule. The protoxid and peroxid of iron do not crystallize in the same form, nor can they be substituted for each other in reactions without radically altering the properties of the resultant compound. On the other hand, all that class of salts known as alums are isomorphous. Not only are their crystals identical in shape, but a crystal of one alum, placed in a saturated solution of another, grows

FIG. 12.

by regular deposition of the second upon its surface. Other alums may be subsequently added to the crystal, a section of which will then exhibit the various salts, layer upon layer.

**Dimorphism.**—Although most substances crystallize, if at all, in one simple form, or in some of its modifications, a few bodies are capable of assuming two crystalline forms, belonging to different systems. Such are said to be **dimorphous**. Thus, sulphur, as obtained by the evaporation of its solution in carbon disulphid, forms octahedra, belonging to the fourth system. When obtained by cooling melted sulphur the crystals are

oblique prisms belonging to the fifth system. Occasional instances of **trimorphism**, of the formation of crystals belonging to three different systems by the same substance, are also known.

Many substances, on assuming the crystalline form, combine with a certain amount of water which exists in the crystal in a solid combination. Thus nearly half of the weight of crystallized alum is water. This water is called **water of crystallization**, and is necessary to the maintenance of the crystalline form, and frequently to the color. If blue vitriol be heated, it loses its water of crystallization, and is converted into an amorphous, white powder. Some crystals lose their water of crystallization on mere exposure to the air. They are then said to **effloresce**. Usually, however, they only lose their water of crystallization when heated. (See p. 66.)

**Allotropy.**—Dimorphism apart, a few substances are known to exist in more than one solid form. These varieties of the same substance exhibit different physical properties, while their chemical qualities are the same in kind. Such modifications are said to be **allotropic**. One or more allotropic modifications of a substance are usually crystalline, the other or others amorphous or vitreous. Sulphur, for example, exists not only in two dimorphous varieties of crystals, but also in a third, allotropic form, in which it is flexible, amorphous, and transparent. Carbon exists in three allotropic forms: two crystalline, the diamond and graphite; the third amorphous.

In passing from one allotropic modification to another, a substance absorbs or gives out heat.

**Solution.**—A solid, liquid, or gas is said to **dissolve**, or form a **solution** with a liquid when the two substances unite to form a homogeneous liquid. Solution may be a purely physical process or a chemical combination.

In **simple or physical solution** there is no modification of the properties of the solvent and dissolved substance, beyond the liquefaction. The latter can be regenerated, in its primitive form, by simple evaporation of the former; and the act of solution is attended by a *diminution of temperature*.

In **chemical solution** the properties of both solvent and dissolved are more or less modified. The dissolved substance cannot be obtained from the solution by simple evaporation of the solvent, unless the compound formed be decomposable, with formation of the original substance, at the temperature of the evaporation. The act of chemical solution is usually attended by an *elevation of temperature*.

The amount of solid, liquid, or gas which a liquid is capable of dissolving by simple solution depends upon the following conditions:

1. *The nature of the solvent and substance to be dissolved.*—No rule can be given, which will apply in a general way to the solvent power of liquids, or to the solubility of substances. Water is of all liquids the best solvent of most substances. In it some substances are so readily soluble that they absorb a sufficiency from the atmosphere to form a solution; as calcium chlorid. Such substances are said to **deliquesce**. Other substances are insoluble in water in any proportion; as barium sulphate. Elementary substances (with the exception of chlorine) are insoluble, or sparingly soluble, in water. Substances rich in carbon are insoluble in water, but soluble in organic liquids.

2. *The temperature* usually has a marked influence on the solubility of a substance. As a rule, water dissolves a greater quantity of a solid substance as the temperature is increased. This increase in solubility is different in the case of different soluble substances. Thus the increase in solubility of the chlorids of barium and of potassium is directly in proportion to the increase of temperature. The solubility of sodium chlorid is almost imperceptibly increased by elevation of temperature. The solubility of sodium sulphate increases rapidly up to 33° (91°.4 F.), above which temperature it again diminishes.

The solubility of gases in water is the greater the lower the temperature, and the greater the pressure.

The amount of a substance that a given quantity of solvent is capable of dissolving at a given temperature is fixed. A solution containing as much of the dissolved substance as it is capable of dissolving is said to be **saturated**. If made at high temperatures it is said to be a *hot saturated*, and if at ordinary temperatures a *cold saturated solution*.

If a hot saturated solution of a salt be cooled, the solid is in most instances separated by crystallization. If, in the case of certain substances, such as sodium sulphate, however, the solution be allowed to cool while undisturbed, no crystallization occurs, and the solution at the lower temperature contains a greater quantity of the solid than it could dissolve at that temperature. Such a solution is said to be **supersaturated**. The contact of particles of solid material with the surface of a supersaturated solution induces immediate crystallization, attended with elevation of temperature.

3. *The presence of other substances already dissolved.*—If to a saturated solution of potassium nitrate, sodium chlorid be added, a further quantity of potassium nitrate may be dissolved. In this case there is double decomposition between the two salts, and the solution contains, besides them, potassium chlorid and sodium nitrate.

4. *The presence of a second solvent.*—If two solvents, *a* and *b*,

incapable of mixing with each other, be brought in contact with a substance which both are capable of dissolving: neither *a* nor *b* takes up the whole of the substance to the exclusion of the other, however greatly the solvent power or bulk of the one may exceed that of the other. The relative quantities taken up by each solvent is in a constant ratio.

**Diffusion of Liquids—Dialysis.**—If a liquid be carefully floated upon the surface of a second liquid, of greater density, with which it is capable of mixing, two distinct layers will at first be formed. Even at perfect rest, mixture will begin immediately, and progress slowly until the two liquids have diffused into each other to form a single liquid whose density is the same throughout.

Substances differ from each other in the rapidity with which

FIG. 13.

they diffuse. Substances capable of crystallization, **crystalloids**, are much more diffusible than those which are incapable of crystallization—**colloids**.

If, in place of bringing two solutions in contact with each other, they be separated by a solid or semi-solid, moist, colloid layer, diffusion takes place in the same way through the interposed layer. Advantage is taken of this fact to separate crystalloids from colloids by the process of **dialysis**. The mixed solutions of crystalloid and colloid are brought into the inner vessel of a dialyser, Fig. 13, whose bottom consists of a layer of moist parchment paper, while the outer vessel is filled with pure water. Water passes into the inner vessel, and the crystalloid passes into the water in the outer vessel. By frequently changing the water in the outer vessel, solutions of the albuminoids or of ferric hydrate, etc., almost entirely free from crystalloids, may be obtained.

**Change of State—Latent Heat.**—The passage of a substance from one form to another is always attended by the absorption or liberation of a definite amount of heat. In passing from the solid to the gaseous form, a body absorbs a definite amount of heat with each change of form. If a given quantity of ice at a temperature below the freezing-point of water be heated, its temperature gradually rises until the thermometer marks 0° (32° F.), at which point it remains stationary until the last particle of ice has disappeared. At that time another rise of the thermometer begins, and continues until 100° (212° F.) is reached (at 760 mm. of barometric pressure), when the water boils, and the thermometer remains stationary until the last particle of water has been converted into steam; after which, if the application of heat be continued, the thermometer again rises. During these two periods of stationary thermometer, heat is taken up by the substance, but is not indicated by the thermometer or by the sense. Not being sensible, it is said to be *latent*, a term which is liable to mislead, as conveying the idea that heat is stored up in the substance *as heat*; such is not the case. During the periods of stationary thermometer the heat is not sensible as heat, for the reason that it is being used up in the *work* required to effect that separation of the particles of matter which constitutes its passage from solid to liquid or from liquid to gas.

The amount of heat required to bring about the passage of a given weight of a given substance from the denser to the rarer form is always the same, and the *temperature* indicated by the thermometer during this passage is always the same for that substance, unless in either case a modification be caused by a variation in pressure.

When a solid is liquefied it is said to *fuse*, or to *melt*.

The degree of temperature indicated by the thermometer while a substance is passing from the solid to the liquid state is called its *fusing-point*; that indicated during its passage from the liquid to the solid form, its *freezing-point*; and that indicated during its passage from the liquid to the gaseous form, its *boiling-point*.

The absorption of heat by a volatilizing liquid is utilized in the arts and in medicine for the production of cold (which is simply the absence of heat), in the manufacture of artificial ice, and in the production of local anæsthesia by the ether-spray. The removal of heat from the body in this way, by the evaporation of perspiration from the surface, is an important factor in the maintenance of the body temperature at a point consistent with life.

When a substance passes from a rarer to a denser form it gives out—liberates—an amount of heat equal to that which it absorbed in its passage in the opposite direction. It is for this reason that,

while we apply heat to convert a liquid into a vapor, we apply cold (or abstract heat) to reduce a gas to a liquid. As a rule, the thermometrical indication is the same in whichever direction the change of form occurs. Some substances, however, solidify at a temperature slightly different from that at which they fuse.

Usually a solid, when sufficiently heated, passes suddenly into the liquid form, and the fusing-point is sharply defined, and easily determined. Some solids, however, like iron and the fats, when heated to the proper degree, are gradually liquefied, first becoming pasty. Such substances have no true fusing-point, as the thermometer passes through several degrees during their liquefaction.

Most solids, when heated, are first converted into liquids, and these into gases. There are, however, some exceptions to this rule. Most vapors, when condensed, pass into the liquid form, and this in turn into the solid. Some substances, however, are condensed from the form of vapor directly to that of solid, in which case they are said to **sublime**.

**Law of Raoult.**—When a substance is dissolved in a liquid the freezing point of the latter is lowered and the amount by which it is lowered varies with the nature and quantity of the dissolved substance. Raoult found that the product obtained by multiplying the amount by which the freezing point of a solution containing a fixed quantity of the dissolved substance (1 gram in 100 c.c.) is lowered by the molecular weight of that substance is nearly constant at 18.5 C. or at 37° C. (See molecular weight, p. 38.) The following are some of the results of Raoult. D.=depression of freezing point in one per cent. solution; M.W.=molecular weight; M.D.=molecular depression.

**Specific Heat.**—Equal volumes of different substances at the same temperature contain different amounts of heat. If two

equal volumes of the same liquid, of different temperatures, be mixed together, the resulting mixture has a temperature which is the mean between the temperatures of the original volumes. If one litre of water at  $4^{\circ}$  ( $39.2^{\circ}$  F.) be mixed with a litre at  $38^{\circ}$  ( $100.4^{\circ}$  F.), the resulting two litres will have a temperature of  $21^{\circ}$  ( $69.8^{\circ}$  F.). Mixtures of equal volumes of different substances, at different temperatures, do not have a temperature which is the

mean of the original temperatures of its constituents. A litre of water at  $4^{\circ}$  ( $39.2^{\circ}$  F.), mixed with a litre of mercury at  $38^{\circ}$  ( $100.4^{\circ}$  F.), forms a mixture whose temperature is  $27^{\circ}$  ( $80.6^{\circ}$  F.). Mercury and water, therefore, differ from each other in their capacity for heat. The same difference exists in a more marked degree between equal *weights* of dissimilar bodies. If a pound of water at  $4^{\circ}$  ( $39.2^{\circ}$  F.) be agitated with a pound of mercury at  $70^{\circ}$  ( $158^{\circ}$  F.), both liquids will have a temperature of  $67^{\circ}$  ( $152.6^{\circ}$  F.).

The amount of heat required to raise a kilo of water from  $0^{\circ}$  C. to  $1^{\circ}$  C. is the unit of heat, and is known as a *calorie*. The *specific heat* of any substance is the amount of heat required to raise one kilo of that substance  $1^{\circ}$  in temperature, expressed in calories.

**Thermometers.** — Temperatures below and slightly above the boiling point of mercury are measured

FIG. 14.

by thermometers. The thermometer is usually a glass tube, having a bulb blown at one extremity and closed at the other. The bulb and part of the tube are filled with mercury, or with alcohol, whose contraction or expansion indicates a fall or rise of temperature. The alcoholic thermometer is used for measuring temperatures below the freezing point of mercury ( $-40^{\circ}$ ), and the mercurial for temperatures between that point and the boiling point of mercury,  $360^{\circ}$  ( $680^{\circ}$  F.). Mercurial thermometers are also constructed to read still higher temperatures, the boiling point of the mercury being raised by filling the upper part of the tube with nitrogen under pressure.

In every thermometer there are two *fixed points*, determined by experiment. The *freezing point* is fixed by immersing the in-

strument in melting ice, and marking the level of the mercury in the tube upon the stem. The boiling point is similarly fixed by suspending the instrument in the steam from boiling water. The instrument is graduated according to one of three scales: the Celsius or Centigrade, the Fahrenheit, and the Réaumur. The freezing point is marked 0° in the Centigrade and Réaumur scales, and 32° in the Fahrenheit. The boiling point is marked 100° in the Centigrade, 212° in the Fahrenheit, and 80° in the Réaumur (Fig. 14). The space between the fixed points is divided into 100 equal degrees in the Centigrade scale, into 180 in the Fahrenheit, and into 80 in the Réaumur. Five degrees Centigrade are therefore equal to nine degrees Fahrenheit.

To convert a thermometric reading in one scale into its equivalent in another the following formulæ are used:

$$\text{Centigrade into Fahrenheit, } \frac{C \times 9}{5} + 32 = F.$$

$$\text{Fahrenheit into Centigrade, } \frac{(F - 32) \times 5}{9} = C.$$

The Réaumur scale is not used in this country. The Fahrenheit scale is used for unscientific, medical and meteorological purposes, in England and America. The Centigrade scale is used

FIG. 15.

among all nations for all scientific purposes other than those mentioned, and for all uses on the continent of Europe, except in Germany.

**Spectroscopy.**—A beam of white light, in passing through a prism, is not only refracted, or bent into a different course, but is also dispersed, or divided into the different colors which constitute the spectrum (Fig. 15). The red rays, being the least de-

FIG. 16.

flected are the **least refrangible**, the violet rays, being the most deflected are the **most refrangible**.

A spectrum is of one of three kinds : 1.) **Continuous**, consisting of a continuous band of colors : red, orange, yellow, green, blue, cyan-blue, and violet. Such spectra are produced by light from white-hot solids and liquids, from gas-light, candle-light, lime-light, and electric light. 2.) **Bright-line spectra**, composed of bright lines upon a dark ground, are produced by glowing vapors and gases. 3.) **Absorption spectra** consist of continuous spectra, crossed by dark lines or bands, and are produced by light passing through a solid, liquid, or gas, capable of absorbing certain rays. Examples of bright-line and absorption spectra are shown in Fig. 16.

The spectrum of sun-light belongs to the third class. It is not

FIG. 17.

continuous, but is crossed by a great number of dark lines, known as **Fraunhofer's lines**, the most distinct of which are designated by letters (No. 1, Fig. 16).

The **spectroscope** consists of four essential parts : 1st, the slit, *a*, Fig. 17 : a linear opening between two accurately straight and parallel knife-edges. 2d, the collimating lens, *b* : a biconvex lens in whose principal focus the slit is placed, and whose object it is to render the rays from the slit parallel before they enter the prism. 3d, the prism, or prisms, *c*, of dense glass, usually of 60°, and so placed that its refracting edge is parallel to the slit. 4th, an observing telescope, *d*, so arranged as to receive the rays as

they emerge from the prisms. Besides these parts spectroscopes are usually fitted with some arbitrary graduation, which serves to fix the location of lines or bands observed.

In direct vision spectroscopes a compound prism is used, so made up of prisms of different kinds of glass that the emerging ray is nearly in the same straight line as the entering ray.

The micro-spectroscope (Fig. 18) is a direct vision spectroscope used as the eye-piece of a microscope. With it the spectra of very small bodies may be observed.

As the spectra produced by different substances are characterized by the positions of the lines or bands, some means of fixing

FIG. 18.

their location is required. The usual method consists in determining their relation to the principal Fraunhofer lines. As, however, the relative positions of these lines vary with the nature of the substance of which the prism is made, although their position with regard to the colors of the spectrum is fixed, no two of the arbitrary scales used will give the same reading.

The most satisfactory method of stating the positions of lines and bands is in **wave-lengths**. The lengths of the waves of rays of different degrees of refrangibility have been carefully deter-

mined, the unit of measurement being the tenth-metre, of which  $10^{10}$  make a metre. The wave-lengths,  $= \lambda$ , of the principal Fraunhofer lines, are :

A.....	7604.00	D.....	5892.12	G.....	4307.25
a.....	7185.00	E.....	5269.13	H <sub>1</sub> .....	3968.01
B.....	6867.00	b.....	5172.00	H <sub>2</sub> .....	3933.00
C.....	6562.01	F.....	4860.72		

The scale of wave-lengths can easily be used with any spectroscope having an arbitrary scale, with the aid of a curve constructed by interpolation. To construct such a curve, paper is used which is ruled into square inches and tenths. The ordinates are marked with a scale of wave-lengths, and the abscisses with the arbitrary scale of the instrument. The position of each principal Fraunhofer line is then carefully determined in terms of the arbitrary scale, and marked upon the paper with a  $\times$  at the point where the line of its wave-length and that of its position in the arbitrary scale cross each other. Through these  $\times$  a curve is then drawn as regularly as possible. In noting the position of an absorption-band, the position of its centre in the arbitrary scale is observed, and its value in wave-lengths obtained from the curve, which, of course, can only be used with the scale and prism for which it has been made.

**Polarimetry.**—A ray of light passing from one medium into another of different density, at an angle other than  $90^\circ$  to the plane of separation of the two media, is deflected from its course, or refracted. Certain substances have the power, not only of deflecting a ray falling upon them in certain directions, but also of dividing it into two rays, which are peculiarly modified. The splitting of the ray is termed **double refraction**, and the altered rays are said to be **polarized**. When a ray of such polarized light meets a mirror held at a certain angle, or a crystal of Iceland spar peculiarly cut (a Nicol's prism), also at a certain angle, it is extinguished. The crystal which produces the polarization is called the **polarizer**, and that which produces the extinction the **analyzer**.

If, when the polarizer and analyzer are so adjusted as to extinguish a ray passing through the former, certain substances are brought between them, light again passes through the analyzer : and in order again to produce extinction, the analyzer must be rotated upon the axis of the ray to the right or to the left. Substances capable of thus influencing polarized light are said to be **optically active**. If, to produce extinction, the analyzer is turned in the direction of the hands of a watch, the substance is said to be **dextrogyrous** ; if in the opposite direction, **lævogyrous**.

The distance through which the analyzer must be turned de-

pend upon the peculiar power of the optically active substance, the length of the column interposed, the concentration, if in solution, and the wave-length of the original ray of light. The **specific rotary power** of a substance is the rotation produced, in degrees and tenths, by one gram of the substance, dissolved in one cubic centimetre of a non-active solvent, and examined in a column one decimetre long. The specific rotary power is determined by dissolving a known weight of the substance in a given volume of solvent, and observing the angle of rotation produced by a column of given length. Then let  $p$  = weight in grams of the substance contained in 1 c.c. of solution;  $l$  the length of the column in decimetres;  $\alpha$  the angle of rotation observed; and  $[\alpha]$  the specific rotary power sought, we have

$$[\alpha] = \frac{\alpha}{pl}.$$

In most instruments monochromatic light, corresponding to the D line of the solar spectrum, is used, and the specific rotary power for that ray is expressed by the sign  $[\alpha]_D$ . The fact that the rotation is right-handed is expressed by the sign +, and that it is left-handed by the sign —.

It will be seen from the above formula that, knowing the value of  $[\alpha]_D$  for any given substance, we can determine the weight of that substance in a solution by the formula

$$p = \frac{\alpha}{[\alpha]_D \times l}.$$

The polarimeter or saccharometer is simply a peculiarly constructed polariscope, used to determine the value of  $\alpha$ .

**Chemical effects of light.**—Many chemical combinations and decompositions are much modified by the intensity, and the kind of light to which the reacting substances are exposed. Hydrogen and chlorine gases do not combine, at the ordinary temperature, in the absence of light; in diffused daylight or gaslight, they unite slowly and quietly; in direct sunlight, or in the electric light, they unite suddenly and explosively. The salts of silver, used in photography, are not decomposed in the dark, but are rapidly decomposed in the presence of organic matter, when exposed to sunlight.

The chemical activity of the different colored rays of which the solar spectrum is composed is not the same. Those which are the most refrangible possess the greatest chemical activity—the greatest actinic power. The visible solar spectrum represents only about one-third of the rays actually emitted from the sun. Two-thirds of the spectrum are invisible as light,

and are only recognizable by their heating effects, or by chemical decompositions which they provoke.

**Galvanic Electricity.**—If two plates, one of pure zinc, the other of pure copper, be immersed in pure, dilute hydrochloric acid, in such a way that the metals are not in contact with each other, there is no action. But if the two metals be connected, outside of the liquid, by a copper wire, the zinc immediately begins to dissolve, and bubbles of hydrogen gas are collected on, and escape from, the surface of the copper, the action continuing so long as the wire connection is maintained, and ceasing so soon as it is interrupted. If a magnetic compass be approached near to the wire, while it is connected with the two plates, the needle will assume a position at right angles to the wire whether the latter be in an east and west position or not. But if the wire be disconnected from either plate, the needle returns to its normal, north and south, position. While the two plates are connected by the wire, an **electrical current** is produced by the chemical action between the zinc and hydrochloric acid, and passes through the liquid and through the wire. A similar electrical current is produced whenever two plates, of different substances, which are conductors of electricity, are connected with each other by a conducting wire, and the free ends dipped into a liquid which has a more intense chemical action upon one plate than upon the other. The plate upon which the greater chemical action is exerted is known as the **negative plate**, or **negative pole**, or **anode**, and, in most batteries consists of zinc. The other plate is called the **collecting plate**, the **positive pole**, or the **cathode**, and usually is made of platinum, carbon or copper. The wires attached to the two plates, as well as any plate, knob or other apparatus in which they terminate are known as the positive and negative electrodes. The current is said to pass from the negative to the positive plate in the battery, and from the positive to the negative in the connecting wire, or apparatus outside the battery. The exciting liquid, the two plates, and the connecting wire, with any conducting apparatus that may be interposed in the course of the wire, is called the **circuit**. The circuit is said to be **closed** when the conducting circle is complete. It is **open**, or **broken**, when it is interrupted at one or more points.

**Electrolysis.**—When a galvanic current of sufficient power passes through a compound liquid, or through a solution of a compound, capable of conducting the current, the compound is decomposed. The decomposition of a compound by this means is called **electrolysis**, and the substance so decomposed is known as the **electrolyte**.

When compounds are subjected to electrolysis the constituent elements are not discharged throughout the mass, although the

decomposition occurs at all points between the electrodes. In compounds made up of two elements only, one element is given off at each of the poles, entirely unmixed with the other, and always from the same pole. Thus, if hydrochloric acid be subjected to electrolysis, pure hydrogen is given off at the negative pole and pure chlorine at the positive pole.

In the case of compounds containing more than two elements, a similar decomposition occurs; one element being liberated at one pole and the remaining group of elements separating at the other. This primary decomposition is frequently modified, as to its final products, by intercurrent chemical reactions. Indeed, the group of elements liberated at one pole is rarely capable of separate existence. When, for instance, a solution of potassium sulphate is subjected to electrolysis, the liquid surrounding the positive electrode becomes acid in reaction, and gives off oxygen. At the same time the liquid on the negative side becomes alkaline, and gives off a volume of hydrogen double that of the oxygen liberated. In the first place the potassium sulphate, which consists of potassium, sulphur, and oxygen, is decomposed into potassium, which separates at the negative pole; and sulphur and oxygen, combined together, which go to the positive pole. The potassium liberated at the negative pole immediately decomposes the surrounding water, forming potash, and liberating hydrogen. The sulphur and oxygen group at the positive pole immediately reacts with water to form sulphuric acid and liberate oxygen.

In the electrolysis of chemical compounds the different elements and groups of elements, such as the sulphur and oxygen group in the example given above, known as *residues* or *radicals*, seem to be possessed of definite electrical characters, and are given off at one or the other pole in preference. Those which are given off at the *positive* or platinum pole are supposed to be negatively electrified, and are therefore known as *electro-negative* or *acidulous* elements or residues. Those given off at the *negative* pole, being positively electrified, are known as *electro-positive* or *basiculous* elements or residues. The following are the electrical characters of the principal elements and residues:

#### ELECTRO-NEGATIVE OR ACIDULOUS.

Oxygen,	Molybdenum,	Arsenic,	Silicon,
Sulphur,	Tungsten,	Chromium,	Osmium,
Nitrogen,	Boron,	Residues of acids remaining after the removal of a number of hydrogen atoms equal to the basicity of the acid.	
Chlorine,	Carbon,		
Iodine,	Antimony,		
Fluorine,	Tellurium,		
Phosphorus,	Niobium,		
Selenium,	Titanium,		

## ELECTRO-POSITIVE OR BASYLOUS.

Hydrogen.	Nickel,	Glucinium,	Silver,
Potassium.	Cobalt,	Yttrium,	Mercury,
Sodium.	Cerium,	Aluminium,	Palladium,
Lithium.	Lead,	Zirconium,	Platinum,
Barium.	Tin,	Manganese,	Rhodium,
Strontium.	Bismuth,	Zinc,	Iridium,
Calcium.	Uranium,	Cadmium,	Gold,
Magnesium.	Copper.	Iron,	Alcoholic radicals.

### CHEMICAL COMBINATION.

**Elements.**—The great majority of the substances existing in and upon the earth may be so decomposed as to yield two or more other substances, distinct in their properties from the substance from whose decomposition they resulted, and from each other. If, for example, sugar be treated with sulphuric acid, it blackens, and a mass of charcoal separates. Upon further examination we find that water has also been produced. From this water we may obtain two gases, differing from each other widely in their properties. Sugar is therefore made up of carbon and the two gases, hydrogen and oxygen; but it has the properties of sugar, and not those of either of its constituent parts. There is no method known by which carbon, hydrogen, and oxygen can be split up, as sugar is, into other dissimilar substances.

**An element is a substance which cannot by any known means be split up into other dissimilar bodies.**

Elements are also called elementary substances or simple substances.

The number of well-characterized elements at present known is sixty-nine. Of these, either free, or united with each other in varied proportion, and in different ways, all matter is composed.

**Laws governing the combination of elements.**—The alchemists, Arabian and European, contented themselves in accumulating a store of knowledge of isolated phenomena, without, as far as we know, attempting, in any serious way, to group them in such a manner as to learn the laws governing their occurrence. It was not until the latter part of the last century, 1777, that Wenzel, of Dresden, implied, if he did not distinctly enunciate, what is known as the law of reciprocal proportions. A few years later, Richter, of Berlin, confirming the work of Wenzel, added to it the law of definite proportions, usually called Dalton's first law. Finally, as the result of his investigations from 1804 to 1808, Dalton added the law of multiple proportions, and, reviewing the work of his predecessors, enunciated the results clearly and distinctly.

Considering these laws, not in the order of their discovery, but in that of their natural sequence, we have :

**THE LAW OF DEFINITE PROPORTIONS.**—The relative weights of elementary substances in a compound are definite and invariable. If, for example, we analyze water, we find that it is composed of eight parts by weight of oxygen for each part by weight of hydrogen, and that this proportion exists in every instance, whatever the source of the water. If, instead of decomposing, or

analyzing water, we start from its elements, and by **synthesis**, cause them to unite to form water, we find that, if the mixture be made in the proportion of eight oxygen to one hydrogen by weight, the entire quantity of each gas will be consumed in the formation of water. But if an excess of either have been added to the mixture, that excess will remain after the combination.

Compounds are substances made up of two or more elements united with each other in definite proportions. Compounds exhibit properties of their own, which differ from those of the constituent elements to such a degree that the properties of a compound can never be deduced from a knowledge of those of the constituent elements. Common salt, for instance, is composed of 39.32 per cent. of the light, bluish-white metal, sodium, and 60.68 per cent. of the greenish-yellow, suffocating gas, chlorine.

Compounds made up of two elements only are called **binary compounds**: those consisting of three elements, **ternary compounds**: those containing four elements, **quaternary compounds**, etc.

A mixture is composed of two or more substances, elements or compounds, mingled in any proportion. The characters of a mixture may be predicated from a knowledge of the properties of its constituents. Thus sugar and water may be mixed in any proportion, and the mixture will have the sweetness of the sugar, and will be liquid or solid, according as the liquid or solid ingredient predominates in quantity.

**THE LAW OF MULTIPLE PROPORTIONS.**—When two elements unite with each other to form more than one compound, the resulting compounds contain simple multiple proportions of one element as compared with a constant quantity of the other.

Oxygen and nitrogen, for example, unite with each other to form no less than five compounds. Upon analysis we find that in these the two elements bear to each other the following relations by weight:

- In the first, 14 parts of nitrogen to 8 of oxygen.
- In the second, 14 parts of nitrogen to  $8 \times 2 = 16$  of oxygen.
- In the third, 14 parts of nitrogen to  $8 \times 3 = 24$  of oxygen.
- In the fourth, 14 parts of nitrogen to  $8 \times 4 = 32$  of oxygen.
- In the fifth, 14 parts of nitrogen to  $8 \times 5 = 40$  of oxygen.

**THE LAW OF RECIPROCAL PROPORTIONS.**—The ponderable quantities in which substances unite with the same substance express the relation, or a simple multiple thereof, in which they unite with each other. Or, as Wenzel stated it, "the weights  $b, b', b''$  of several bases which neutralize the same weight  $a$  of an acid are the same which will neutralize a constant weight  $a'$  of another acid; and the weights  $a, a', a''$  of different acids which

neutralize the same weight  $b$  of a base are the same which will neutralize a constant weight of another base  $b$ ." For example : 71 parts of chlorin combine with 40 parts of calcium, and 16 parts of oxygen also combine with 40 parts of calcium, therefore 71 parts of chlorin combine with 16 parts of oxygen, or the two elements combine in the proportion of some simple multiples of 71 and 16.

**The Atomic Theory.**—The laws of Wenzel, Richter, and Dalton, given above, are simply generalized statements of certain groups of facts, and, as such, not only admit of no doubt, but are the foundations upon which chemistry as an exact science is based. Dalton, seeking an explanation of the reason of being of these facts, was led to adopt the view held by the Greek philosopher, Democritus, that matter was not infinitely divisible. He retained the name *atom* (*ἄτομος* = indivisible), given by Democritus to the ultimate particles, of which matter was supposed by him to be composed : but rendered the idea more precise by ascribing to these atoms real magnitude, and a definite weight, and by considering elementary substances as made up of atoms of the same kind, and compounds as consisting of atoms of different kinds.

This hypothesis, the first step toward the atomic theory as entertained to-day, afforded a clear explanation of the numerical results stated in the three laws. If hydrogen and oxygen always unite together in the proportion of one of the former to eight of the latter, it is because, said Dalton, the compound consists of an atom of hydrogen, weighing 1, and an atom of oxygen, weighing 8. If, again, in the compounds of nitrogen and oxygen, we have the two elements uniting in the proportion  $14 : 8$ — $14 : 8 \times 2$ — $14 : 8 \times 3$ — $14 : 8 \times 4$ — $14 : 8 \times 5$ , it is because they are severally composed of an atom of nitrogen weighing 14, united to 1, 2, 3, 4, or 5 atoms of oxygen, each weighing 8. Further, that compounds do not exist in which any fraction of 8 oxygen enters, because 8 is the weight of the indivisible atom of oxygen.

Dalton's hypothesis of the existence of atoms as definite quantities did not, however, meet with general acceptance. Davy, Wollaston, and others considered the quantities in which Dalton had found the elements to unite with each other, as mere *proportional numbers* or *equivalents*, as they expressed it, nor is it probable that Dalton's views would have received any further recognition until such time as they might have been exhumed from some musty tome, had their publication not been closely followed by that of the results of the labors of Humboldt and of Gay Lussac, concerning the *volumes* in which gases unite with each other.

In the form of what are known as Gay Lussac's laws, these results are :

First.—There exists a simple relation between the volumes of gases which combine with each other.

Second.—There exists a simple relation between the sum of the volumes of the constituent gases, and the volume of the gas formed by their union. For example :

- 1 volume chlorine unites with 1 volume hydrogen to form 2 volumes hydrochloric acid.
- 1 volume oxygen unites with 2 volumes hydrogen to form 2 volumes vapor of water.
- 1 volume nitrogen unites with 3 volumes hydrogen to form 2 volumes ammonia.
- 1 volume oxygen unites with 1 volume nitrogen to form 2 volumes nitric acid.
- 1 volume oxygen unites with 2 volumes nitrogen to form 2 volumes nitrous acid.

Berzelius, basing his views upon these results of Gay Lussac, modified the hypothesis of Dalton and established a distinction between the *equivalents* and *atoms*. The composition of water he expressed, in the notation which he was then introducing, as being  $H_2O$ , and not  $HO$  as Dalton's hypothesis called for. As, however, Berzelius still considered the atom of oxygen as weighing 8, he was obliged also to consider the atoms of hydrogen and of certain other elements as double atoms—a fatal defect in his system, which led to its overthrow, and to the re-establishment of the formula  $HO$  for water.

It was reserved to Gerhardt to clearly establish the distinction between atom and molecule; to observe the bearing of the discoveries of Avogadro and Ampère upon chemical philosophy; and thus to establish the atomic theory as entertained at present.

As a result of his investigations in the domain of organic chemistry, Gerhardt found that, if Dalton's equivalents be adhered to, whenever carbon dioxid or water is liberated by the decomposition of an organic substance, it is invariably in double equivalents, never in single ones. Always  $2CO_2$  or  $2H_2O$ , or some multiple thereof, never  $CO_2$  or  $HO$ . He further found that if the equivalents  $C=6$ ,  $H=1$ , and  $O=8$  be retained, the formulæ became such that the equivalents of carbon are always divisible by two. In fact, he found the same objections to apply to the notation then in use that had been urged against that of Berzelius.

In 1811, Avogadro, from purely physical researches, had been enabled to state the law which is now known by his name, to the effect that equal volumes of all gases, under like conditions of temperature and pressure, contain equal numbers of molecules.

This law is also known as the law of Ampère, the French physicist having enunciated it about the same time as, and independently of, his Italian collaborer.

In the hands of Gerhardt this law, in connection with those of Gay Lussac, became the foundation of what is sometimes called the "new chemistry." Bearing in mind Avogadro's law, we may

translate the first three combinations given in the table on p. 33 into the following :

- 1 molecule chlorine unites with 1 molecule hydrogen, to form 2 molecules hydrochloric acid.
- 1 molecule oxygen unites with 2 molecules hydrogen, to form 2 molecules vapor of water.
- 1 molecule nitrogen unites with 3 molecules hydrogen, to form 2 molecules ammonia.

But the ponderable quantities in which these combinations take place are :

35.5 chlorine to . . . . . 1 hydrogen.  
 16 oxygen to . . . . . 2 hydrogen.  
 14 nitrogen to . . . . . 3 hydrogen.

And as single molecules of hydrogen, oxygen, and nitrogen are in these combinations subdivided to form 2 molecules of hydrochloric acid, water, and ammonia, it follows that these molecules must each contain two equal quantities of hydrogen, oxygen, and nitrogen, less in size than the molecules themselves. And, further, as in these instances each molecule contains two of these smaller quantities, or **atoms**, the relation between the weights of the molecules must be also the relation between the weights of the atoms, and we may therefore express the combinations thus :

- 1 atom chlorine weighing 35.5 unites with 1 atom hydrogen weighing 1 ;
- 1 atom oxygen weighing 16 unites with 2 atoms hydrogen weighing 2 ;
- 1 atom nitrogen weighing 14 unites with 3 atoms hydrogen weighing 3 ;

and consequently, if the atom of hydrogen weighs 1, that of chlorine weighs 35.5, that of oxygen 16, and that of nitrogen 14.

**Atomic Weight.**—The distinction between molecules and atoms may be expressed by the following definitions :

**A molecule is the smallest quantity of any substance that can exist in the free state.**

**An atom is the smallest quantity of an elementary substance that can enter into a chemical reaction.**

The molecule is always made up of atoms, upon whose nature, number, and arrangement with regard to each other, the properties of the substance depend. In an elementary substance the atoms composing the molecules are the same in kind, and usually two in number. In compound substances they are dissimilar, and vary in quantity from two in a simple compound, like hydrochloric acid, to hundreds or thousands in more complex substances.

The word **atom** can only be used in speaking of an elementary body, and that only while it is passing through a reaction. The term **molecule** applies indifferently to elements and compounds.

The atoms have definite relative weights : and upon an exact determination of these weights depends the entire science of quantitative analytical chemistry. (See stoichiometry, p. 44.)

They have been determined by repeated and careful analyses of perfectly pure compounds of the elements, and express the weight of one atom of the element as compared with the weight of one atom of hydrogen, that being the lightest element known. It is also the weight of a volume of the element, in the form of gas, which would occupy the same volume, under like pressure and temperature, as an amount of hydrogen weighing one. What the *absolute weight* of an atom of any element may be we do not know, nor would the knowledge be of any service did we possess it.

The following table contains a list of the elements at present known, with their atomic weights :

## ELEMENTS.

NAME.	A. symbol.	B. Atomic Weight.	NAME.	A. symbol.	B. Atomic Weight.
Aluminium...	Al.	27.02	Molybdenum..	Mo.	95.5
Antimony.....	Sb.	120	Nickel.....	Ni.	58
Arsenic.....	As.	74.9	Niobium.....	Nb.	94
Barium.....	Ba.	136.8	Nitrogen.....	N.	14.044
Bismuth.....	Bi.	206.5	Osmium.....	Os.	198.5
Boron.....	Bo.	11	Oxygen.....	O.	16
Bromin.....	Br.	79.952	Palladium.....	Pd.	105.7
Cadmium.....	Cd.	111.8	Phosphorus...	P.	31
Cesium.....	Cs.	132.6	Platinum.....	Pt.	194.4
Calcium.....	Ca.	40	Potassium.....	K.	39.137
Carbon.....	C.	11.974	Rhodium.....	Rh.	104.1
Cerium.....	Ce.	141	Rubidium.....	Rb.	85.3
Chlorin.....	Cl.	35.457	Ruthenium....	Ru.	104.2
Chromium.....	Cr.	52.4	Samarium.....	Sm.	150
Cobalt.....	Co.	58.9	Scandium.....	Sc.	44
Copper.....	Cu.	63.2	Selenium.....	Se.	78.8
Davyium.....	Da.	154	Silicon.....	Si.	28
Didymium....	D.	144.78	Silver.....	Ag.	107.675
Erbium.....	E.	165.9	Sodium.....	Na.	22.998
Fluorin.....	F.	19	Strontium.....	Sr.	87.4
Gallium.....	Ga.	68.8	Sulphur.....	S.	31.984
Germanium...	Gr.	72.32	Tantalum.....	Ta.	182
Glucinum.....	Gl.	9	Tellurium.....	Te.	128
Gold.....	Au.	196.2	Thallium.....	Tl.	203.7
Hydrogen.....	H.	1	Thorium.....	Th.	233
Indium.....	In.	113.4	Tin.....	Sn.	117.7
Iodin.....	I.	126.85	Titanium.....	Ti.	49.85
Iridium.....	Ir.	192.7	Tungsten.....	W.	183.6
Iron.....	Fe.	55.9	Uranium.....	U.	238.5
Lanthanium...	La.	138.5	Vanadium.....	V.	51.3
Lead.....	Pb.	206.92	Ytterbium.....	Yb.	172.7
Lithium.....	Li.	7	Yttrium.....	Y.	89.8
Magnesium...	Mg.	24	Zinc.....	Zn.	64.9
Manganese...	Mn.	54	Zirconium.....	Zr.	89.6
Mercury.....	Hg.	199.7			

In some cases the results of analyses are such as would agree with two values as the atomic weight of an element equally well. In this case we can decide which is the correct value by the law of Dulong and Petit. These observers found that while the atomic weights of the elements vary greatly from each other, the specific heats (see p. 19) differ from each other in an opposite manner, and to such an extent that the product obtained by multiplying the two together does not vary much from 6.4. This product is known as the atomic heat. When it is not possible to determine by analysis which of two numbers is the correct atomic weight of an element, that one is selected which, when multiplied by the specific heat, gives a result most nearly approaching 6.4.

The atomic heats of boron, carbon, silicon, sulphur, and phosphorus are subject to great variations, as is shown in the following table :

		Specific Heat.	Atomic Heat.
<b>BORON.</b>			
Crystallized	at - 39.6°.....	0.1915	2.11
Crystallized	at + 76.7°.....	0.2737	3.01
Crystallized	at + 233.2°.....	0.3663	3.99
Amorphous.....		0.255	2.81

**CARBON.**

Diamond	at - 50.5°.....	0.0635	0.76
Diamond	at + 140°.....	0.2218	2.66
Diamond	at + 985°.....	0.4589	5.51
Graphite	at - 50.3°.....	0.1138	1.37
Graphite	at + 138.5°.....	0.2542	3.05
Graphite	at + 977.9°.....	0.4670	5.60
Wood charcoal.....		0.2415	2.90

**SILICON.**

Crystallized	at - 39.8°.....	0.1360	3.81
Crystallized	at + 128.7°.....	0.1964	5.50
Crystallized	at + 232.4°.....	0.2029	5.68
Fused	at + 100°.....	0.175	4.90

**SULPHUR.**

Orthorhombic	at + 45°.....	0.163	5.22
Orthorhombic	at + 99°.....	0.1776	5.68
Liquid	at + 150°.....	0.234	7.49
Recently fused	at + 98°.....	0.20259	6.48

PHOSPHORUS.		Specific Heat.	Atomic Heat.
Yellow	at - 78°.....	0.174	5.39
Yellow	at + 36°.....	0.202	6.26
Liquid	at + 100°.....	0.212	6.57
Amorphous	at + 98°.....	0.170	5.27

It will be observed that, as the temperature of the *solid* element is increased, the atomic heat more nearly approaches 6.4. It will further be noticed that those elements with which the perturbations occur are those which are capable of existing in two or more allotropic forms (see p. 15). As in the passage of an element from one allotropic condition to another, absorption or liberation of heat always takes place, as the result of "interior work;" it is probable that these perturbations are due to a constant tendency of the element to pass from one allotropic condition to another.

The atomic heats of those elementary gases which have only been liquefied by enormous cold and pressure are tolerably constant at about 2.4.

**Molecular Weight.**—The molecular weight of a substance is the weight of its molecule as compared with the weight of an atom of hydrogen. It is also, obviously, the sum of the weights of all the atoms making up the molecule.

A very ready means of determining the molecular weight of a gaseous substance or of one which may be converted into vapor, is based upon Avogadro's law. The sp. gr. of a gas is the weight of a given volume as compared with that of an equal volume of hydrogen. But these equal volumes contain equal numbers of molecules (p. 33), and therefore, in determining the sp. gr. of a gas, we obtain the weight of its molecule as compared with that of a molecule of hydrogen; and, as the molecule contains two atoms of hydrogen, while one atom of hydrogen is the unit of comparison, it follows that the specific gravity of a gas compared with hydrogen, multiplied by two, is its molecular weight.

For example, the gas acetylene and the liquid benzene each contain 92.31 per cent. of carbon, and 7.69 per cent. of hydrogen; which is equivalent to 24 parts, or two atoms of carbon; and 2 parts, or two atoms of hydrogen. The sp. gr. of acetylene, referred to hydrogen = 2, is 13; its molecular weight is, therefore, 26, and its molecule contains two atoms of carbon and two atoms of hydrogen. The sp. gr. of vapor of benzene is 39; its molecular weight is, therefore, 78, and its molecule contains six atoms of carbon and six atoms of hydrogen.

When a substance is not capable of being volatilized, its molecular weight may be obtained by determining its percentage

composition by analysis, and selecting that value which is nearest in obedience to the law of Raoult (see p. 19).

The vapor densities of comparatively few elements are known :

	Vapor Density.	Atomic Weight.	Molecular Weight.
Hydrogen.....	1	1	2
Oxygen.....	16	16	32
Sulphur.....	32	32	64
Selenium.....	82	79	164
Tellurium.....	130	128	260
Chlorin.. .. .	35.5	35.5	71
Bromin.....	80	80	160
Iodin.....	127	127	254
Phosphorus... ..	63	31	124
Arsenic.....	150	75	300
Nitrogen... ..	14	14	28
Potassium.....	39	39	78
Cadmium.....	56	112	112
Mercury.....	100	200	200

The atomic weight being, in most of the above instances, equal to the vapor density, and to half the molecular weight, it may be inferred that *the molecules of these elements consist of two atoms*. Noticeable discrepancies exist in the case of four elements. The molecular weights of phosphorus and arsenic, as obtained from their vapor densities, are not double, but four times as great as their atomic weights. The molecules of phosphorus and arsenic are, therefore, supposed to contain four atoms. Those of cadmium and mercury contain but one atom.

**Valence or Atomicity.**—It is known that the atoms of different elements possess different powers of combining with and of replacing atoms of hydrogen. Thus :

One atom of chlorin combines with one atom of hydrogen.

One atom of oxygen combines with two atoms of hydrogen.

One atom of nitrogen combines with three atoms of hydrogen.

One atom of carbon combines with four atoms of hydrogen.

The valence, atomicity, or equivalence of an element is the saturating power of one of its atoms as compared with that of one atom of hydrogen.

Elements may be classified according to their valence into—

Univalent elements, or monads.....	Cl'
Bivalent elements, or dyads.....	O''
Trivalent elements, or triads.....	B'''
Quadrivalent elements, or tetrads.....	Civ
Quinivalent elements, or pentads.....	P <sup>v</sup>
Sexvalent elements, or hexads.....	W <sup>vi</sup>

Elements of even valence, *i. e.*, those which are bivalent, quadrivalent, or sexvalent, are sometimes called **artiads**; those of uneven valence being designated as **perissads**.

In notation the valence is indicated, as above, by signs placed to the right and above the symbol of the element.

But the valence of the elements is not fixed and invariable. Thus, while chlorin and iodine each combine with hydrogen, atom for atom, and in those compounds are consequently univalent, they unite with each other to form two compounds—one containing one atom of iodine and one of chlorin, the other containing one atom of iodine and three of chlorin. Chlorine being univalent, iodine is obviously trivalent in the second of these compounds. Again, phosphorus forms two chlorides, one containing three, the other five atoms of chlorin to one of phosphorus.

In view of these facts, we must consider, either: 1, that the valence of an element is that which it exhibits in its most saturated compounds, as phosphorus in the pentachloride, and that the lower compounds are non-saturated, and have free valences; or 2, that the valence is variable. The first supposition depends too much upon the chances of discovery of compounds in which the element has a higher valence than that which might be considered the maximum to-day. The second supposition—notwithstanding the fact that, if we admit the possibility of two distinct valences, we must also admit the possibility of others—is certainly the more tenable and the more natural. *In speaking, therefore, of the valence of an element, we must not consider it as an absolute quality of its atoms, but simply as their combining power in the particular class of compounds under consideration.* Indeed, compounds are known in whose molecules the atoms of one element exhibit two distinct valences. Thus, ammonium cyanate contains two atoms of nitrogen: one in the ammonium group is quinquivalent, one in the acid radical is trivalent.

When an element exhibits different valences, these differ from each other by two. Thus, phosphorus is trivalent or quinquivalent: platinum is bivalent or quadrivalent.

**Symbols—Formulæ—Equations.**—Symbols are conventional abbreviations of the names of the elements, whose purpose it is to introduce simplicity and exactness into descriptions of chemical actions. They consist of the initial letter of the Latin name of the element, to which is usually added one of the other letters. If there be more than two elements whose names begin with the same letter, the single-letter symbol is reserved for the commonest element. Thus, we have nine elements whose names begin with C: of these the commonest is Carbon, whose symbol is C; the others have double-letter symbols, as Chlorine, Cl; Cobalt, Co; Copper, Cu (Cuprum), etc.

These symbols do not indicate simply an indeterminate quantity, but represent one atom of the corresponding element.

When more than one atom is spoken of, the number of atoms which it is desired to indicate is written either before the symbol or, in small figures, after and below it. Thus, H indicates one atom of hydrogen; 2Cl, two atoms of chlorine; C<sub>4</sub>, four atoms of carbon, etc.

What the symbol is to the element, the formula is to the compound. By it the number and kind of atoms of which the molecule of a substance is made up are indicated. The simplest kind of formulæ are what are known as empirical formulæ, which indicate only the kind and number of atoms which form the compound. Thus, HCl indicates a molecule composed of one atom of hydrogen united with one atom of chlorine; 5H<sub>2</sub>O, five molecules, each composed of two atoms of hydrogen and one atom of oxygen, the number of molecules being indicated by the proper numeral placed before the formula, in which place it applies to all the symbols following it. Sometimes it is desired that a numeral shall apply to a part of the symbols only, in which case they are enclosed in parentheses; thus, Al<sub>2</sub> (SO<sub>4</sub>)<sub>3</sub> means twice Al and three times SO<sub>4</sub>.

For other varieties of formulæ, see pp. 50-52.

**Equations** are combinations of formulæ and algebraic signs so arranged as to indicate a chemical reaction and its results. The signs used are the plus and equality signs; the former being equivalent to "and," and the second meaning "have reacted upon each other and have produced." The substances entering into the reaction are placed before the equality sign, and the products of the reaction after it; thus, the equation

means, when translated into ordinary language: two molecules of potash, each composed of one atom of potassium, one atom of hydrogen, and one atom of oxygen, *and* one molecule of sulphuric acid, composed of one atom of sulphur, four atoms of oxygen, and two atoms of hydrogen, *have reacted upon each other and have produced* one molecule of potassium sulphate, composed of one atom of sulphur, four atoms of oxygen, and two atoms of potassium, *and* two molecules of water, each composed of two atoms of hydrogen and one atom of oxygen.

As no material is ever lost or created in a reaction, the number of each kind of atom occurring before the equality sign in an equation must always be the same as that occurring after it. In writing equations they should always be proved by examining whether the half of the equation before the equality sign contains the same number of each kind of atom as that after the equality sign. If it do not the equation is incorrect.

**Acids, Bases, and Salts.**—All ternary and quaternary mineral substances have one of three functions.

The function of a substance is its chemical character and relationship, and indicates certain general properties, reactions and decompositions which all substances possessing the same function possess or undergo alike. Thus, in mineral chemistry we have acids, bases, and salts; in organic chemistry alcohols, aldehydes, ketones, ethers, etc.

An acid is a compound of an electro-negative element or residue with hydrogen; which hydrogen it can part with in exchange for an electro-positive element without formation of a base. An acid may also be defined as a compound body which evolves water by its action upon pure caustic potash or soda.

No substance which does not contain hydrogen can, therefore, be called an acid.

The basicity of an acid is the number of replaceable hydrogen atoms contained in its molecule.

A monobasic acid is one containing a single replaceable atom of hydrogen, as nitric acid,  $\text{HNO}_3$ ; a dibasic acid is one containing two such replaceable atoms, as sulphuric acid,  $\text{H}_2\text{SO}_4$ ; a tri-basic acid is one containing three replaceable hydrogen atoms, as phosphoric acid,  $\text{H}_3\text{PO}_4$ . Polybasic acids are such as contain more than one atom of replaceable hydrogen.

Hydracids are acids containing no oxygen: oxacids or oxyacids contain both hydrogen and oxygen.

The term base is regarded by many authors as applicable to any compound body capable of neutralizing an acid. It is, however, more consistent with modern views to limit the application of the name to such compound substances as are capable of entering into double decomposition with acids to form salts and water. They may be considered as one or more molecules of water in which one-half of the hydrogen has been replaced by an electro-positive element or radical: or as compounds of such elements or radicals with one or more groups,  $\text{OH}$ . Being thus considered as derivable from water, they are also known as basic hydrates. They have the general formula,  $\text{Mn}(\text{OH})_n$ . They are monatomic, diatomic, triatomic, etc., according as they contain one, two, three, etc., groups **oxhydriyl** ( $\text{OH}$ ).

A double decomposition is a reaction in which both of the reacting compounds are decomposed to form two new compounds.

Sulphobases, or hydrosulphids, are compounds in all respects resembling the bases, except that in them the oxygen of the base is replaced by sulphur.

Salts are substances formed by the substitution of basylous radicals or elements for a part or all of the replaceable hydrogen of an acid. They are always formed, therefore, when bases and

acids enter into double decomposition. They are not, as was formerly supposed, formed by the union of a metallic with a non-metallic oxid, but, as stated above, by the substitution of one or more atoms of an element or radical for the hydrogen of the acid. Thus, the compound formed by the action of sulphuric acid upon quicklime is not  $\text{SO}_3\text{CaO}$ , but  $\text{CaSO}_4$ , formed by the interchange of atoms :

and not

it is, therefore, **calcium sulphate**, and not **sulphate of lime**.

The term **salt**, as used at present, applies to the compounds formed by the substitution of a basylous element for the hydrogen of *any* acid; and indeed, as used by some authors, to the acids themselves, which are considered as salts of hydrogen. It is probable, however, that eventually the name will be limited to such compounds as correspond to acids whose molecules contain more than two elements. Indeed, from the earliest times of modern chemistry a distinction has been observed between the **haloid salts**, *i.e.* those the molecules of whose corresponding acids consist of hydrogen, united with one other element, on the one hand; and the **oxysalts**, the salts of the oxacids, *i.e.*, those into whose composition oxygen enters, on the other hand. This distinction, however, has gradually fallen into the background, for the reason that the methods and conditions of formation of the two kinds of salts are usually the same *when the basylous element belongs to that class usually designated as metallic*.

There are, however, important differences between the two classes of compounds. There exist compounds of all of the elements corresponding to the hydracids, binary compounds of chlorine, bromine, iodine, and sulphur. There is, on the other hand, a large class of elements the members of which are incapable of forming salts corresponding to the oxacids. No salt of an oxacid with any one of the elements usually classed as metalloids (excepting hydrogen) has been obtained.

Haloid salts may be formed by direct union of their constituent elements; oxysalts are never so produced.

**Action of Acids and Bases on Salts, and of Salts on each other.**

—If an acid be added to a solution of a salt whose acid it nearly equals in chemical activity, the salts of both acids and the free

acids themselves will probably exist in the solution, provided both acids and salts are soluble. Thus :

If an acid be added to a solution of a salt whose acid it greatly exceeds in activity, the salt is decomposed, with formation of the salt of the stronger acid and liberation of the weaker acid ; both acids and salts being soluble :

If to a solution of a salt whose acid is insoluble in the solvent used, an acid be added capable of forming a soluble salt with the basylous element, such soluble salt is formed and the acid is deposited :

If to a salt whose acid is volatile at the existing temperature, an acid capable of forming with the basylous element a salt fixed at the same temperature be added, the fixed salt is formed and the volatile acid expelled. Thus, with the application of heat :

If to a solution of a salt an acid be added which is capable of forming an insoluble salt with the base, such insoluble salt is formed and precipitated :

If to a solution of a salt whose basylous element is insoluble a soluble base is added, capable of forming a soluble salt with the acid, such soluble salt is formed, with precipitation of the insoluble base :

If a base be added to a solution of a salt with whose acid it is capable of forming an insoluble salt, such insoluble salt is formed and precipitated, and the base of the original salt, if insoluble, is also precipitated :

When solutions of two salts, the acids of both of which form soluble salts with both bases, are mixed, the resultant liquid contains the four salts :

or in some other proportion.

If solutions of two salts, the acid of one of which is capable of uniting with the base of the other to form an insoluble salt, are mixed, such insoluble salt is precipitated :

**Stoichiometry** ( $\sigma\tau\omicron\chi\epsilon\iota\omicron\nu$  = an element;  $\mu\epsilon\tau\rho\omicron\nu$  = a measure)—in its strict sense refers to the law of definite proportions, and to its applications. In a wider sense, the term applies to the mathematics of chemistry, to those mathematical calculations by which the quantitative relations of substances acting upon each other, and of the products of such reactions are determined.

A chemical reaction can always be expressed by an equation, which, as it represents not only the nature of the materials involved, but also the number of molecules of each, is a quantitative as well as a qualitative statement.

Let it be desired to determine how much sulphuric acid will be required to completely decompose 100 parts of sodium nitrate, and what will be the nature and quantities of the products of the decomposition. First the equation representing the reaction is constructed :

which shows that one molecule of sulphuric acid decomposes two molecules of sodium nitrate, with the formation of one molecule of sodium sulphate and two of nitric acid. The quantities of the different substances are, therefore, represented by their molecular weights, or some multiple thereof, which are in turn obtained by adding together the atomic weights of the constituent atoms :

Consequently, 98 parts  $\text{H}_2\text{SO}_4$  decompose 170 parts  $\text{NaNO}_3$ , and produce 142 parts  $\text{Na}_2\text{SO}_4$  and 126 parts  $\text{HNO}_3$ . To find the result as referred to 100 parts  $\text{NaNO}_3$ , we apply the simple proportion :

$$\begin{array}{lcl} 170 : 100 :: 98 : 57.64 - 57.64 = \text{parts } \text{H}_2\text{SO}_4 \text{ required.} \\ 170 : 100 :: 142 : 83.53 - 83.53 = \text{ " } \text{Na}_2\text{SO}_4 \text{ produced.} \\ 170 : 100 :: 126 : 74.11 - 74.11 = \text{ " } \text{HNO}_3 \text{ " } \end{array}$$

As in writing equations (see p. 40), the work should always be proved by adding together the quantities on each side of the equality sign, which should equal each other :  $98 + 170 = 268 = 142 + 126$  or  $57.64 + 100 = 157.64 = 83.53 + 74.11 = 157.64$ .

In determining quantities as above, regard must be had to the purity of the reagents used, and, if they be crystallized, to the amount of water of crystallization (see p. 15) they contain.

Let it be desired to determine how much crystallized cupric sulphate can be obtained from 100 parts of sulphuric acid of 92% strength. As cupric sulphate crystallizes with five molecules of water of crystallization the reaction occurs according to the equation :

98 parts of 100%  $\text{H}_2\text{SO}_4$  will produce, therefore, 249 parts of crystallized cupric sulphate. But as the acid liquid used contains only 92 parts of true  $\text{H}_2\text{SO}_4$  in 100 : 100 parts of such acid will yield 233.75 parts of crystallized sulphate, for  $98 : 92 :: 249 : 233.75$ .

In gravimetric quantitative analysis the substance whose quantity is to be determined is converted into an insoluble compound, which is then purified, dried, and weighed (see Part III.), and from this weight the desired result is calculated.

Let the problem be to determine what percentage of silver is contained in a silver coin. Advantage is taken of the formation of the insoluble silver chlorid. A piece of the coin is then chipped off and weighed : Weight of coin used = 2.5643 grams. The chip is then dissolved in nitric acid, forming a solution of silver nitrate. From this solution the silver is precipitated as chlorid, by the addition of hydrochloric acid, according to the equation :

AgNO <sub>3</sub> Silver nitrate.	+ HCl Hydrochloric acid.	= AgCl Silver chlorid.	+ HNO <sub>3</sub> Nitric acid.
108×1=108	1	108	1×1= 1
14×1= 14	35.5	35.5	14×1=14
16×3= 48			16×3=48
<u>170</u>	<u>36.5</u>	<u>143.5</u>	<u>63</u>

$$170 + 36.5 = 206.5 = 143.5 + 63.$$

The silver chlorid is collected, dried, and weighed :

Weight of coin used.....2.5643 grams.  
Weight of AgCl obtained.....3.0665 "

as 143.5 grams AgCl contain 108 grams Ag—143.5:108::3.0665 : 2.3078—2.5643 grams of the coin contain 2.3078 grams of silver, or 90%—2.5643 : 100 :: 2.3078 : 8.

**Nomenclature.**—The names\* of the elements are mostly of Greek derivation, and have their origin in some prominent property of the substance. Thus, *phosphorus*, *φῶς*, *light*, and *οἰστρον*, *to bear*. Some are of Latin origin, as *silicon*, from *silex*, flint : some of Gothic origin, as *iron*, from *iarn* : and others are derived from modern languages, as *potassium* from *pot-ash*. Very little system has been followed in naming the elements, beyond applying the termination *ium* to the metals, and *in* or *on* to the metalloids : and even to this rule we find such exceptions as a metal called *manganese* and a metalloid called *sulphur*.

The names of *compound substances* were formerly chosen upon the same system, or rather lack of system, as those of the elements. So long as the number of compounds with which the chemist had to deal remained small, the use of these fanciful appellations, conveying no more to the mind than perhaps some unimportant quality of the substances to which they applied, gave rise to comparatively little inconvenience. In these later days, however, when the number of compounds known to exist, or whose existence is shown by approved theory to be possible, is practically infinite, some systematic method of nomenclature has become absolutely necessary.

The principle of the system of nomenclature at present used is that the name shall convey the composition and character of the substance.

Compounds consisting of two elements, or of an element and a radical only, *binary compounds*, are designated by compound names made up of the name of the more electro-positive, followed by that of the more electro-negative, in which the termination *id* has been substituted for the termination, *in*, *on*, *ogen*, *ygen*.

\* For rules governing orthography and pronunciation of chemical terms see Appendix A.

*orus, ium, and ur.* For example: the compound of potassium and chlorin is called potassium *chlorid*, that of potassium and oxygen, potassium *oxid*, that of potassium and phosphorus, potassium *phosphid*.

In a few instances the older name of a compound is used in preference to the one which it should have under the above rule, for the reason that the substance is one which is typical of a number of other substances, and therefore deserving of exceptional prominence. Such are *ammonia*,  $\text{NH}_3$ ; *water*,  $\text{H}_2\text{O}$ .

When, as frequently happens, two elements unite with each other to form more than one compound, these are usually distinguished from each other by prefixing to the name of the element varying in amount the Greek numeral corresponding to the number of atoms of that element, as compared with a *fixed* number of atoms of the other element.

Thus, in the series of compounds of nitrogen and oxygen, most of which contain two atoms of nitrogen,  $\text{N}_2$  is the standard of comparison, and consequently the names are as follows:

$\text{N}_2\text{O}$	=Nitrogen <i>monoxid</i> .
$\text{NO}$ ( $=\text{N}_2\text{O}_2$ )	=Nitrogen <i>dioxid</i> .
$\text{N}_2\text{O}_3$	=Nitrogen <i>trioxid</i> .
$\text{NO}_2$ ( $=\text{N}_2\text{O}_4$ )	=Nitrogen <i>tetroxid</i> .
$\text{N}_2\text{O}_5$	=Nitrogen <i>pentoxid</i> .

Another method of distinguishing two compounds of the same two elements consists in terminating the first word in *ous*, in that compound which contains the less proportionate quantity of the more electro-negative element, and in *ic* in that containing the greater proportion; thus:

$\text{SO}_2$	=Sulphurous oxid.
$\text{SO}_3$	=Sulphuric oxid.

$\text{Hg}_2\text{Cl}_2$ (2Hg : 2Cl)	=Mercurous chlorid.
$\text{HgCl}_2$ (2Hg : 4Cl)	=Mercuric chlorid.

This method, although used to a certain extent in speaking of compounds composed of two elements of Class II. (see p. 54), is used chiefly in speaking of binary compounds of elements of different classes.

In naming the *oxacids* the word *acid* is used, preceded by the name of the electro-negative element other than oxygen, to which a prefix or suffix is added to indicate the degree of oxidation. If there be only two, the least oxidized is designated by the suffix *ous*, and the more oxidized by the suffix *ic*, thus:

$\text{HNO}_2$	=Nitrous acid.	.
$\text{HNO}_3$	=Nitric acid.	

If there be more than two acids, formed in regular series, the least oxidized is designated by the prefix *hypo* and the suffix *ous*; the next by the suffix *ous*; the next by the suffix *ic*; and the most highly oxidized by the prefix *per* and the suffix *ic*; thus:

Certain elements, such as sulphur and phosphorus, exist in acids which are derived from those formed in the regular way, and which are specially designated.

The names of the oxy-salts are derived from those of the acids by dropping the word *acid*, changing the termination of the other word from *ous* into *ite*, or from *ic* into *ate*, and prefixing the name of the electro-positive element or radical; thus:

Acids whose molecules contain more than one atom of replaceable hydrogen are capable of forming more than one salt with electro-positive elements, or radicals, whose valence is less than the basicity of the acid. Ordinary phosphoric acid, for instance, contains in each molecule three atoms of basic hydrogen, and consequently is capable of forming three salts by the replacement of one, two, or three of its hydrogen atoms, by one, two, or three atoms of a univalent metal. To distinguish these the Greek prefixes *mono*, *di*, and *tri* are used, the termination *ium* of the name of the metal being changed to *ic*, thus:

The first is also called *dihydropotassic phosphate*, and the second, *hydrodipotassic phosphate*.

In the older works, salts in which the hydrogen has not been entirely displaced are sometimes called **bisalts** (bicarbonates), or **acid salts**; those in which the hydrogen has been entirely displaced being designated as **neutral salts**.

Some elements, such as mercury, copper, and iron, form two distinct series of salts. These are distinguished, in the same way as the acids, by the use of the suffix *ous* in the names of those

containing the less proportion of the electro-negative group, and the suffix *ic* in those containing the greater proportion, *e.g.* :

$(\text{Cu}_2)_2\text{SO}_4$ . . . . .	$(1\text{SO}_4 : 4\text{Cu}) = \text{Cuprous sulphate.}$
$\text{Cu}_2\text{SO}_4$ . . . . .	$(2\text{SO}_4 : 4\text{Cu}) = \text{Cupric sulphate.}$
$\text{FeSO}_4$ . . . . .	$(2\text{SO}_4 : 2\text{Fe}) = \text{Ferrous sulphate.}$
$(\text{Fe}_2)(\text{SO}_4)_3$ . . . . .	$(3\text{SO}_4 : 2\text{Fe}) = \text{Ferric sulphate.}$

The names, **basic salts**, **subsals**, and **oxysalts** have been applied indifferently to salts, such as the lead subacetates, which are compounds containing the normal acetate and the hydrate or oxid of lead ; and to salts such as the so-called bismuth subnitrate, which is a nitrate, not of bismuth, but of the univalent radical  $(\text{Bi}'''\text{O}'')$ .

By **double salts** are meant such as are formed by the substitution of different elements or radicals for two or more atoms of replaceable hydrogen of the acid, such as ammonio-magnesian phosphate,  $\text{PO}_4\text{Mg}''(\text{NH}_4)'$ .

**Radicals.**—Many compounds contain groups of atoms which pass from one compound to another, and, in many reactions, behave like elementary atoms. Such groups are called **radicals**, or **compound radicals**.

Marsh gas has the composition  $\text{CH}_4$ . By acting upon it in suitable ways we can cause the atom of carbon, accompanied by three of the hydrogen atoms, to pass into a variety of other compounds, such as :  $(\text{CH}_3)\text{Cl}$  ;  $(\text{CH}_3)\text{OH}$  ;  $(\text{CH}_3)_2\text{O}$  ;  $\text{C}_2\text{H}_5\text{O}_2$  ;  $(\text{CH}_3)$ . Marsh gas, therefore, consists of the radical  $(\text{CH}_3)$  combined with an atom of hydrogen :  $(\text{CH}_3)\text{H}$ .

It is especially among the compounds of carbon that the existence of radicals comes into prominent notice. They, however, occur in inorganic substances also. Thus the nitric acid molecule consists of the radical  $\text{NO}_2$ , combined with the group  $\text{OH}$ .

Like the elements, the radicals possess different valences, depending upon the number of unsatisfied valences which they contain. Thus the radical  $(\text{CH}_3)$  is univalent, because three of the four valences of the carbon atom are satisfied by atoms of hydrogen, leaving one free valence. The radical  $(\text{PO})$  of phosphoric acid is trivalent, because two of the five valences of the phosphorus atom are satisfied by the two valences of the bivalent oxygen atom, leaving three free valences.

In notation the radicals are usually enclosed in brackets, as above, to indicate their nature. The names of radicals terminate in *yl* or in *gen* : thus :  $(\text{CH}_3) = \text{methyl}$  ;  $(\text{CN}) = \text{cyanogen}$ .

The terms *radical* and *residue*, although sometimes used as synonyms, are not such in speaking of electrical decompositions (see p. 27). Thus the **radical** of sulphuric acid is  $\text{SO}_2$  ; but when

sulphuric acid is electrolyzed it is decomposed into hydrogen and the residue  $\text{SO}_4$ .

**Composition and Constitution.**—The characters of a compound depend not only upon the kind and number of its atoms, but also upon the manner in which they are attached to each other. There are, for instance, two substances, each having the empirical formula  $\text{C}_2\text{H}_4\text{O}_2$ , one of which is a strong acid, the other a neutral ether. As the molecule of each contains the same number and kind of atoms, the differences in their properties must be due to differences in the manner in which the atoms are linked together.

The composition of a compound is the number and kind of atoms contained in its molecule; and is shown by its empirical formula.

The constitution of a compound is the number and kind of atoms and their relations to each other, within its molecule; and is shown by its typical or graphic formula.

In the system of typical formulæ all substances are considered as being so constituted that their rational formulæ may be referred to one of three classes or types, or to a combination of two of these types. These three classes, being named after the most common substance occurring in each, are expressed thus:

The hydrogen type.	The water type.	The ammonia type.
$\begin{array}{c} \text{H} \\ \text{H} \end{array} \}$	$\begin{array}{c} \text{H} \\ \text{H} \end{array} \} \text{O}$	$\begin{array}{c} \text{H} \\ \text{H} \\ \text{H} \end{array} \} \text{N}$
$\begin{array}{c} \text{H}_2 \\ \text{H}_2 \end{array} \}$	$\begin{array}{c} \text{H}_2 \\ \text{H}_2 \end{array} \} \text{O}_2$	$\begin{array}{c} \text{H}_2 \\ \text{H}_2 \\ \text{H}_2 \end{array} \} \text{N}_2$
etc.,	etc.,	etc.,

it being considered that the formula of any substance of known constitution can be indicated by substituting the proper element, or radical, for one or more of the atoms of the type, thus:

$\begin{array}{c} \text{Cl} \\ \text{H} \end{array} \}$	$\begin{array}{c} (\text{C}_2\text{H}_5)' \\ \text{H} \end{array} \} \text{O}$	$\begin{array}{c} (\text{C}_2\text{H}_5)' \\ \text{H} \\ \text{H} \end{array} \} \text{N}$	$\begin{array}{c} \text{Cl}_2 \\ \text{Ca} \end{array} \}$	$\begin{array}{c} (\text{SO}_2)'' \\ \text{H}_2 \end{array} \} \text{O}_2$	$\begin{array}{c} (\text{CO})'' \\ \text{H}_2 \\ \text{H}_2 \end{array} \} \text{N}_2$
Hydrochloric acid.	Alcohol.	Ethylamin.	Calcium chlorid.	Sulphuric acid.	Urea.

Typical formulæ are of great service in the classification of compound substances, as well as to indicate, to a certain degree, their nature and the method of the reactions into which they enter. Thus in the case of the two substances mentioned above, as both having the composition  $\text{C}_2\text{H}_4\text{O}_2$ , we find on examination that one contains the group  $(\text{CH}_3)'$ , while the other contains the

group  $(C_2H_3O)$ . The difference in their constitution at once becomes apparent in their typical formulæ,  $\begin{matrix} (CHO) \\ (CH_3) \end{matrix} \left\{ \begin{matrix} O \\ O \end{matrix} \right.$  and  $\begin{matrix} (C_2H_3O) \\ H \end{matrix} \left\{ \begin{matrix} O \\ O \end{matrix} \right.$ , indicating differences in their properties, which we find upon experiment to exist. The first substance is neutral in reaction and possesses no acid properties; it closely resembles a salt of an acid having the formula  $\begin{matrix} (CHO) \\ H \end{matrix} \left\{ \begin{matrix} O \\ O \end{matrix} \right.$ . The second substance, on the other hand, has a strongly acid reaction, and markedly acid properties, as indicated by the oxidized radical and the extra-radical hydrogen. It is capable of forming salts by the substitution of an atom of a univalent, basylous element for its single replaceable atom of hydrogen:  $\begin{matrix} (C_2H_3O)' \\ Na \end{matrix} \left\{ \begin{matrix} O \\ O \end{matrix} \right.$ .

Although typical formulæ have been and still are of great service, many cases arise, especially in treating of the more complex organic substances, in which they do not sufficiently indicate the relations between the atoms which constitute the molecule, and thus fail to convey a proper idea of the nature of the substance. Considering, for example, the ordinary lactic acid, we find its composition to be  $C_3H_4O_3$ , which, expressed typically, would be  $\begin{matrix} (C_3H_4O)'' \\ H_2 \end{matrix} \left\{ \begin{matrix} O_2 \\ O \end{matrix} \right.$ , a constitution supported by the fact that the radical  $(C_3H_4O)''$  may be obtained in other compounds, as  $\begin{matrix} (C_3H_4O)' \\ (Cl_2) \end{matrix} \left\{ \begin{matrix} O \\ O \end{matrix} \right.$ . This constitution, however, cannot be the true one, because in the first place, lactic acid is not dibasic, but monobasic; and in the second place, there is another acid, called paralactic acid, having an identical composition, yet differing in its products of decomposition. These differences in the properties of the two acids must be due to a different *arrangement* of atoms in their molecules, a view which is supported by the sources from which they are obtained and the nature of their products of decomposition.

To express the constitution of such bodies *graphic formulæ* are used, in which the position of each atom in relation to the others is set forth. The constitution of the two lactic acids would be expressed by graphic formulæ in this way:

or,

It must be understood that these graphic formulæ are simply intended to show the relative attachments of the atoms, and are in nowise intended to convey the idea that the molecule is spread out upon a flat surface, with the atoms arranged as indicated in the diagram.

Great care and much labor are required in the construction of these graphic formulæ, the positions of the atoms being determined by a close study of the methods of formation, and of the products of decomposition of the substance under consideration. Naturally, in a matter of this nature, there is always room for differences of opinion—indeed, the entire atomic theory is open to question, as is the theory of gravitation itself. But whatever may be advanced, two facts cannot be denied: first, that chemistry owes its advancement within the past half-century to the atomic theory, which to-day is more in consonance with observed facts than any substitute which can be offered; second, that without the use of graphic formulæ it is impossible to offer any adequate explanation of the reactions which we observe in dealing with the more complex organic substances.

In chemistry, as in other sciences, a sharp distinction must always be made between facts and theories: the former, once observed, are immutable additions to our knowledge; the latter are of their nature subject to change with our increasing knowledge of facts. We have every reason for believing, however, that the supports upon which the atomic theory rests are such that, although it may be modified in its details, its essential features will remain unaltered.

**Classification of the Elements.**—Berzelius was the first to divide all the elements into two great classes, to which he gave the names **metals** and **metalloids**. The metals, being such substances as are opaque, possess what is known as metallic lustre, are good conductors of heat and electricity, and are electro-positive: the metalloids, on the other hand, such as are gaseous, or, if solid, do not possess metallic lustre, have a comparatively low power of conducting heat and electricity, and are electro-negative.

This division, based upon purely physical properties, which, in many cases, are ill-defined, has become insufficient. Several elements formerly classed under the above rules with the metals,

resemble the metalloids in their chemical characters much more closely than they do any of the metals. Indeed, by the characters mentioned above, it is impossible to draw any line of demarcation which shall separate the elements distinctly into two groups.

The classification of the elements should be such that each group shall contain elements whose *chemical* properties are similar—the *physical* properties being considered only in so far as they are intimately connected with the chemical. The arrangement of elements into groups is not equally easy in all cases. Some groups, as the chlorine group, are sharply defined, while the members of others differ from each other more widely in their properties. The positions of most of the more recently discovered elements are still uncertain, owing to the imperfect state of our knowledge of their properties.

The method of classification which we will adopt, and which we believe to be more natural than any hitherto suggested, is based upon the chemical properties of the oxids and upon the valence of the elements. We abandon the division into metals and metalloids, and substitute for it a division into four great classes, according to the nature of the oxids and the existence or non-existence of oxysalts. In the first of these classes hydrogen and oxygen are placed together, for the reason that, although they differ from each other in many of their properties, they together form the basis of our classification, and may, for this and other reasons, be regarded as **typical elements**. They both play important parts in the formation of acids, and neither would find a suitable place in either of the other classes. Our primary division would then be as follows :

**Class I.—Typical elements.**

**Class II.—Elements whose oxids unite with water to form acids, never to form bases. Which do not form oxysalts.**

This class contains all the so-called metalloids except hydrogen and oxygen.

**Class III.—Elements whose oxids unite with water, some to form bases, others to form acids. Which form oxysalts.**

**Class IV.—Elements whose oxids unite with water to form bases ; never to form acids. Which form oxysalts.**

In this class are included the more strongly electro-positive metals.

Within the classes a further subdivision is made into groups, each group containing those elements within the class which have equal valences, which form corresponding compounds, and whose *chemical characters* are otherwise similar.

For the sake of convenience the term **metal** is retained to apply

to the members of Classes III. and IV. ; the term **non-metal** being used for those belonging to Class II.

#### Class I.

GROUP I.—Hydrogen.

GROUP II.—Oxygen.

#### Class II.

GROUP I.—Fluorin, chlorin, bromin, iodin.

GROUP II.—Sulphur, selenium, tellurium.

GROUP III.—Nitrogen, phosphorus, arsenic, antimony.

GROUP IV.—Boron.

GROUP V.—Carbon, silicon.

GROUP VI.—Vanadium, niobium, tantalum.

GROUP VII.—Molybdenum, tungsten, osmium (?).

#### Class III.

GROUP I.—Gold.

GROUP II.—Cromium, manganese, iron.

GROUP III.—Glucinium, aluminium, scandium, gallium, indium.

GROUP IV.—Uranium.

GROUP V.—Lead.

GROUP VI.—Bismuth.

GROUP VII.—Titanium, zirconium, tin.

GROUP VIII.—Palladium, platinum.

GROUP IX.—Rhodium, ruthenium, iridium.

#### Class IV.

GROUP I.—Lithium, sodium, potassium, rubidium, cæstum, silver.

GROUP II.—Thallium.

GROUP III.—Calcium, strontium, barium.

GROUP IV.—Magnesium, zinc, cadmium.

GROUP V.—Nickel, cobalt.

GROUP VI.—Copper, mercury.

GROUP VII.—Yttrium, cerium, ytterbium, lanthanum, didymium, erbium.

GROUP VIII.—Thorium.

# PART II.

## SPECIAL CHEMISTRY.

### CLASS I.

#### TYPICAL ELEMENTS.

##### HYDROGEN—OXYGEN.

ALTHOUGH, in a strict sense, hydrogen is regarded by most chemists as the one and only type-element—that whose atom is the unit of atomic and molecular weights—the important part which oxygen plays in the formation of those compounds whose nature forms the basis of our classification, its acid-forming power in organic compounds, and the differences existing between its properties and those of the elements of the sulphur group, with which it is usually classed, warrant us in separating it from the other elements and elevating it to the position it here occupies.

##### HYDROGEN.

*Symbol*—**H**—*Univalent*—*Atomic weight* = 1—*Molecular weight* = 2—*Sp. gr.* = 0.06926A\*—*One litre weighs* 0.0896 gram†—100 cubic inches weigh 2.1496 grains‡—1 gram measures 11.16 litres†—1 grain measures 46.73 cubic inches‡—*Name derived from* *hydro* = *water*, and *genna* = *I produce*—*Discovered by Cavendish in 1766.*

**Occurrence.**—Occurs free in volcanic gases, in fire-damp, occluded in meteorites, in the gases exhaled from the lungs, and in those of the stomach and intestine. In combination in water, hydrogen sulphid, ammoniacal compounds, and in many organic substances.

**Preparation.**—(1.) By electrolysis of water, H is given off at the negative pole. Utilized when pure H is required.

---

\*Air = 1. When the sp. gr. is referred to H = 1, A is replaced by H.

†At 0° C. and 760 mm. barometric pressure.

‡At 60° F. and 30 inches bar. pressure.

(2.) By the disassociation of water at very high temperatures.

(3.) By the decomposition of water by certain metals. The alkali metals decompose water at the ordinary temperature :

Some other metals, such as iron and copper, effect the decomposition only at high temperatures :

(4.) By decomposition of water, passed over red-hot coke :

or at a higher temperature :

(5.) By decomposition of mineral acids, in the presence of water, by zinc and certain other metals :

The water serves to dissolve the zinc sulphate. Chemically

FIG. 19.

pure zinc, or zinc whose surface has been covered with an alloy of zinc and mercury, does not decompose the acid unless it forms part of a galvanic battery whose circuit is closed. The zines of galvanic batteries are therefore covered with the alloy mentioned—are amalgamated—to prevent waste of zinc and acid.

This is the method usually resorted to for obtaining H. The gas so obtained is, however, contaminated with small quantities of other gases, hydrogen phosphid, sulphid, and arsenid.

FIG. 20.

Hydrogen, carbon dioxide, hydrogen sulphid, and other gases produced by the action of a liquid upon a solid at ordinary temperatures, are best prepared in one of the forms of apparatus shown in Figs. 19, 20, and 21.

The solid material is placed in the larger bottle (Fig. 19), or, over a layer of broken glass about five centimetres thick, in the bottle A (Fig. 20). The liquid reagent is from time to time introduced by the funnel tube, Fig. 19; or the bottle B, Fig. 20, is filled with it. The wash-bottles are partially filled with water to arrest any liquid or solid impurity. The apparatus, Figs. 20 and 21, have the advantage of being always ready for use. When the stopcock is open the gas escapes. When it is closed the internal pressure depresses the level of the liquid in A into the layer of broken glass, and the action is arrested. Kipp's apparatus, Fig. 21, is another convenient form of constant apparatus. The solid reagent is placed in the central bulb.

FIG. 21.

(6.) By heating together a mixture of zinc dust and dry slacked lime :

**Properties.**—*Physical.*—Hydrogen is a colorless, odorless, tasteless gas : 14.47 times lighter than air, being the lightest substance

known. The weight of a litre, 0.0896 gram, is called a *crith* (*crith* = barleycorn). It is almost insoluble in water and alcohol. It conducts heat and electricity better than any other gas. In obedience to the law: **The diffusibility of two gases varies inversely as the square roots of their densities**, it is the most rapidly diffusible of gases. The rapidity with which this diffusion takes place renders the use of hydrogen, which has been kept for even a short time in gas-bags or gasometers, dangerous. At  $-140$  ( $-229$  F.), under a pressure of 650 atmospheres, it forms a steel-blue liquid.

Certain metals have the power of absorbing large quantities of hydrogen, which is then said to be *occluded*. Palladium absorbs 376 volumes at the ordinary temperature; 932 vols. at  $90$  ( $194$  F.) and 526 vols. at  $245$  ( $473$  F.). The occluded gas is driven off by the application of heat, and possesses great chemical activity, similar to that which it has when in the nascent state. This latter quality, and the fact that heat is liberated during the occlusion, would seem to indicate that the gas is contained in the metal, not in a mere physical state of condensation, but in chemical combination.

*Chemical.*—Hydrogen exhibits no great tendency to combine with other elements at ordinary temperatures. The only one with which it combines under such circumstances is chlorine, and then only under the influence of light. It does not support combustion, but, when ignited, burns with a pale blue and very hot flame; the result of the combination being water. Mixtures of hydrogen and oxygen explode violently on the approach of flame, or by the passage of the electric spark, the explosion being caused by the sudden expansion of the vapor of water formed, under the influence of the heat of the reaction. Hydrogen also unites with oxygen when brought in contact with spongy platinum. Many compounds containing oxygen give up that element when heated in an atmosphere of hydrogen:

The removal of oxygen from a compound is called a *reduction* or *deoxidation*.

At the instant that H is liberated from its compounds it has a deoxidizing power similar to that which ordinary H possesses only at elevated temperatures, and its tendency to combine with other elements is greater than under other conditions. The greater energy of H, and of other elements as well, in this **nascent state**, may be thus explained. Free H exists in the form of molecules, each one of which is composed of two atoms, but at the instant of its liberation from a compound, it is in the form

of individual atoms, and that portion of force required to split up the molecule into atoms, necessary when free H enters into reaction, is not required when the gas is in the nascent state.

In its physical and chemical properties, this element more closely resembles those usually ranked as metals than it does those forming the class of metalloids, among which it is usually placed. Its conducting power, its appearance in the liquid form, as well as its relation to the acids, which may be considered as salts of H, tend to separate it from the metalloids.

**Analytical Characters.**—(1.) Burns with a faintly blue flame, which deposits water on a cold surface brought in contact with it; (2.) Mixed with oxygen, explodes on contact with flame, producing water.

### OXYGEN.

*Symbol = O—Bivalent—Atomic weight = 16; molecular weight = 32—Sp. gr. = 1.10563 A (calculated = 1.1088); 15.95 H; sp. gr. of liquid = 0.9787—One litre weighs 1.4300 grams = 16 eriths—100 cubic inches weigh 34.27 grains—Name derived from  $\gamma\epsilon\upsilon\omega$  = acid, and  $\pi\rho\omicron\upsilon\epsilon\iota\varsigma$  = I produce—Discovered by Mayow in 1674; re-discovered by Priestley in 1774.*

**Occurrence.**—Oxygen is the most abundant of the elements. It exists free in atmospheric air; in combination in a great number of substances, mineral, vegetable, and animal.

**Preparation.**—(1.) By heating certain oxids:

This was the method used by Priestley. 100 grams of mercuric oxid produce 5.16 litres of oxygen:

The black oxid of manganese is heated to redness in an iron or clay retort (Scheele, 1775); and 100 grams yield 8.51 litres of oxygen.

(2.) By the electrolysis of water, acidulated with sulphuric acid, O is given off at the positive pole.

(3.) By the action of sulphuric acid upon certain compounds rich in O: manganese dioxid, potassium dichromate, and plumbic peroxid:

100 grams of manganese dioxid produce 12.82 litres of O.

(4.) By decomposing  $\text{H}_2\text{SO}_4$  at a red heat,  $2\text{H}_2\text{SO}_4 = 2\text{SO}_2 + 2\text{H}_2\text{O} + \text{O}_2$ .

One kilo  $\text{H}_2\text{O}_2$  (3%) and 500 cc. dilute  $\text{H}_2\text{SO}_4$  (1:5) are placed in the generating flask and 56 grams  $\text{K}_2\text{Mn}_2\text{O}_8$ , dissolved in  $\text{H}_2\text{O}$ , are gradually added. With these quantities 20 litres O are obtained.

(7.) By the action of dilute hydrochloric acid upon a mixture of 2 parts barium peroxid, 1 part manganese dioxid, and 1 part plaster of Paris, compressed into cubes about 1½ cent. square.

Methods 6 and 7 have the advantage that heat is not required, and the forms of apparatus, Figs. 19, 20, and 21, may be used.

**Properties.**—*Physical.*—Oxygen is a colorless, odorless, tasteless gas, soluble in water in the proportion of 7.08 cc. in 1 litre of water at 14.868 (60 F.), somewhat more soluble in absolute alco-

FIG. 22.

hol. It liquefies at  $-140^\circ$  ( $-229^\circ$  F.) under a pressure of 200 atmospheres. Liquid oxygen boils at  $-187.4^\circ$  ( $-294.5^\circ$  F.) at the ordinary pressure.

*Chemical.*—Oxygen is characterized, chemically, by the strong tendency which it exhibits to enter into combination with other elements. It forms binary compounds with all elements except fluorin and bromin. With most elements it unites directly, especially at elevated temperatures. In many instances this union is attended by the appearance of light, and always by the extrication of heat. The luminous union of O with another element constitutes the familiar phenomenon of **combustion**, and is the principal source from which we obtain so-called artificial heat and light. A body is said to be **combustible** when it is capable of so energetically combining with the oxygen of the air as to liber-

ate light as well as heat. Gases are said to be **supporters of combustion**, when combustible substances will unite with them, or with some of their constituents, the union being attended with the appearance of heat and light. The distinction between combustible substances and supporters of combustion is, however, one of mere convenience. The action taking place between the two substances, one is as much a party to it as the other. A jet of air burns in an atmosphere of coal-gas as readily as a jet of coal-gas burns in air.

The compounds of oxygen—the **oxids**—are divisible into three groups :

1. **Anhydrids**—oxids capable of combining with water to form *acids*. Thus *sulphuric anhydrid*,  $\text{SO}_3$ , unites with water to form *sulphuric acid*,  $\text{H}_2\text{SO}_4$ .

The term anhydrid is not limited in application to *binary* compounds, but applies to any substance capable of combining with water to form an acid. Thus the compound  $\text{C}_4\text{H}_6\text{O}_3$  is known as acetic anhydrid, because it combines with water to form acetic acid :  $\text{C}_4\text{H}_6\text{O}_3 + \text{H}_2\text{O} = 2\text{C}_2\text{H}_4\text{O}_2$ . (See compounds of arsenic and sulphur.)

2. **Basic Oxids** are such as combine with water to form bases. Thus, calcium oxid,  $\text{CaO}$ , unites with water to form calcium hydrate,  $\text{CaH}_2\text{O}_2$ .

3. **Saline, neutral, or indifferent oxids** are such as are neither acid nor basic in character. In some instances they are essentially neutral, as in the case of the protoxid of hydrogen, or water. In other cases they are formed by the union of two other oxids, one basic, the other acid in quality, such as the red oxid of lead,  $\text{Pb}_3\text{O}_4$ , formed by the union of a molecule of the acidulous peroxid,  $\text{PbO}_2$ , with two of the basic protoxid,  $\text{PbO}$ . It is to oxids of this character that the term "saline" properly applies.

The process of respiration is very similar to combustion, and as oxygen gas is the best supporter of combustion, so, in the diluted form in which it exists in atmospheric air, it is not only the best, but the only supporter of animal respiration. (See carbon dioxid.)

**Analytical Characters.**—1.) A glowing match-stick bursts into flame in free oxygen. 2.) Free O, when mixed with nitrogen dioxid, produces a brown gas.

**Ozone.**—*Allotropic oxygen.*—Air through which discharges of static electricity have been passed, and oxygen obtained by the decomposition of water (if electrodes of gold or platinum be used), have a peculiar odor, somewhat resembling that of sulphur, which is due to the conversion of a part of the oxygen into ozone.

Ozone is produced : 1.) By the decomposition of water by the

battery. 2.) By the slow oxidation of phosphorus in damp air. 3.) By the action of concentrated sulphuric acid upon barium dioxid. 4.) By the passage of silent electric discharges through air or oxygen.

In the preparation of ozonized oxygen the best results are obtained by passing a slow current of oxygen through an apparatus made entirely of glass and platinum, cooled by a current of cold water, and traversed by the invisible discharge of an induction coil.

Pure, liquid ozone has been obtained by subjecting ozonized oxygen to the temperature of liquid oxygen at the atmospheric pressure. It is a dark blue liquid, almost opaque in layers 2 mm. thick, which is not decomposed at the ordinary temperature, but converted into a blueish gas.

When oxygen is ozonized it contracts slightly in volume, and when the ozone is removed from ozonized oxygen by mercury or potassium iodid the volume of the gas is not diminished. These facts, and the great chemical activity of ozone, have led chemists to regard it as condensed oxygen; the molecule of ozone being represented thus (OOO), while that of ordinary oxygen is (OO).

Ozone is very sparingly soluble in water, insoluble in solutions of acids and alkalies. In the presence of moisture it is slowly converted into oxygen at 100° (212° F.), a change which takes place rapidly and completely at 237° (459° F.). It is a powerful oxidant; it decomposes solutions of potassium iodid with formation of potassium hydrate, and liberation of iodine: it oxidizes all metals except gold and platinum, in the presence of moisture; it decolorizes indigo and other organic pigments, and acts rapidly upon rubber, cork, and other organic substances.

**Analytical Characters.**—1.) Neutral litmus paper, impregnated with solution of potassium iodid, is turned blue when exposed to air containing ozone. The same litmus paper without iodid is not affected. 2.) Manganous sulphate solution is turned brown by ozone. 3.) Solutions of thallous salts are colored yellow or brown by ozone. 4.) Paper impregnated with fresh tincture of natural (unpurified) gnaiaecum is colored blue by ozone. 5.) Paper impregnated with solution of manganous sulphate, or lead hydrate, or palladium chlorid is colored dark brown or black by ozone.

When inhaled, air containing 0.07 gram of ozone per litre causes intense coryza and hæmoptysis. It is probable that ozone is by no means as constant a constituent of the atmosphere as was formerly supposed. (See Hydrogen dioxid.)

## Compounds of Hydrogen and Oxygen.

Two are known—hydrogen oxid or water,  $H_2O$ ; hydrogen per-oxid or oxygenated water,  $H_2O_2$ .

## Water.

$H_2O$ —*Molecular weight*=18—*Sp. gr.*=1—*Vapor density*=0.6218  
A; *calculated*=0.6234—*Composition discovered by Priestley in*  
1780.

**Occurrence.**—In unorganized nature  $H_2O$  exists in the gaseous form in atmospheric air and in volcanic gases; in the liquid form very abundantly; and as a solid in snow, ice, and hail.

As **water of crystallization** it exists in definite proportion in certain crystals, to the maintenance of whose shape it is necessary.

In the organized world  $H_2O$  forms a constituent part of every tissue and fluid.

**Formation.**—Water is formed: 1. By union, brought about by elevation of temperature, of one vol. O with two vols. H.

2. By burning H, or substances containing it, in air or in O.

3. By heating organic substances containing H to redness with cupric oxid, or with other substances capable of yielding O. This method of formation is utilized to determine the amount of H contained in organic substances.

4. When an acid and a hydrate react upon each other to form a salt:

5. When a metallic oxid is reduced by hydrogen:

c. In the reduction and oxidation of many organic substances.

Pure  $H_2O$  is not found in nature. When required pure it is separated from suspended matters by filtration, and from dissolved substances by distillation.

**Properties.**—*Physical.*—With a barometric pressure of 760 mm.  $H_2O$  is solid below 0° (32° F.); liquid between 0° (32° F.) and 100° (212° F.); and gaseous above 100° (212° F.). When  $H_2O$  is enclosed in capillary tubes, or is at complete rest, it may be cooled to -15° (5° F.) without solidifying. If, while at this temperature, it be agitated, it solidifies instantly, and the temperature suddenly rises to 0° (32° F.). The melting-point of ice is lowered 0.0075° (0.0135° F.) for each additional atmosphere of pressure.

The boiling-point is subject to greater variations than the freezing-point. It is the lower as the pressure is diminished, and

the higher as it is increased. Advantage is taken of the reduced boiling point of solutions in vacuo for the separation of substances, such as cane sugar, which are injured at the temperature of boiling  $\text{H}_2\text{O}$ . On the other hand, the increased temperature that may be imparted to liquid  $\text{H}_2\text{O}$  under pressure is utilized in many processes, in the laboratory and in the arts, for effecting solutions and chemical actions which do not take place at lower temperatures. The boiling-point of  $\text{H}_2\text{O}$  holding solid matter in solution is higher than that of pure  $\text{H}_2\text{O}$ , the degree of increase depending upon the amount and nature of the substance dissolved. On the other hand, mixtures of  $\text{H}_2\text{O}$  with liquids of lower boiling-point boil at temperatures less than  $100^\circ$  ( $212^\circ \text{F.}$ ). Although the conversion of water into water-gas takes place most actively at  $100^\circ$  ( $212^\circ \text{F.}$ ), water and ice evaporate at all temperatures.

Water is the best solvent we have, and acts in some instances as a simple solvent, in others as a chemical solvent.

Vapor of water is colorless, transparent, and invisible. Sp. gr. 0.6234 A or 9 H. A litre of vapor of water weighs 0.8064. The latent heat of vaporization of water is 536.5; that is, as much heat is required to vaporize 1 kilo. of water at  $100^\circ$  as would suffice to raise 536.5 kilos. of water  $1^\circ$  in temperature. In passing from the liquid to the gaseous state, water expands 1,696 times in volume.

*Chemical.*—Water may be shown to consist of 1 vol. O and 2 vols. H, or 8 by weight of O and 1 by weight of H, either by analysis or synthesis.

**Analysis** is the reducing of a compound to its constituent elements.

**Synthesis** is the formation of a compound from its elements. A partial synthesis is one in which a complex compound is produced from a simpler one, but not from the elements.

Water may be resolved into its constituent gases: 1st. By electrolysis of acidulated water: H being given off at the negative and O at the positive pole. 2d. By passing vapor of  $\text{H}_2\text{O}$  through a platinum tube heated to whiteness, or through a porcelain tube heated to about  $1,100^\circ$ . 3d. By the action of the alkali metals. Hydrogen is given off, and the metallic hydrate remains in solution in an excess of  $\text{H}_2\text{O}$ . 4th. By passing vapor of  $\text{H}_2\text{O}$  over red-hot iron. Oxid of iron remains and H is given off.

Water combines with oxids to form new compounds, some of which are acids and others bases, known as hydrates, or hydroxids.

A hydrate is a compound formed by the replacement of part of the hydrogen of water by another element or radical.

The group of atoms HO contained in the hydrates is known as hydroxyl.

The hydrates of the electro-negative elements and radicals are **acids**; most of those of the electro-positive elements and radicals are **basic hydrates**.

Certain substances, in assuming the crystalline form, combine with a definite proportion of water, which is known as **water of crystallization**, and whose presence, although necessary to the maintenance of certain physical characters, such as color and crystalline form, does not modify their chemical reactions. In many instances a portion of the water of crystallization may be driven off at a comparatively low temperature, while a much higher temperature is required to expel the remainder. This latter is known as **water of constitution**.

The symbol Aq (Latin, *aqua*) is frequently used to designate the water of crystallization, the water of constitution being indicated by  $H_2O$ . Thus  $MgSO_4 \cdot H_2O + 6 Aq$  represents magnesium sulphate with one molecule of water of constitution and six molecules of water of crystallization. We consider it preferable, however, as the distinction between water of crystallization and water of constitution is only one of degree and not of kind, to use the symbol Aq to designate the sum of the two; thus,  $MgSO_4 + 7 Aq$ .

Water decomposes the chlorids of the second class of elements (those of carbon only at high temperatures and under pressure); while the chlorids of the elements of the third and fourth classes are either insoluble, or soluble without decomposition.

**Natural Waters.**—Water, as it occurs in nature, always contains solid and gaseous matter in solution and frequently solids in suspension.

Natural waters may be classified, according to the nature and quantity of foreign matters which they contain, into **potable** and **unpotable** waters. To the first class belong rain-water, snow- and ice-water, spring-water (fresh), river-water, lake-water, and well-water. To the second class belong stagnant waters, sea-water, and the waters of mineral springs.

*Rain-water* is usually the purest of natural waters, so far as dissolved solids are concerned, containing very small quantities of the chlorids, sulphates, and nitrates of sodium and ammonium. Owing to the large surface exposed during condensation, rain-water contains relatively large quantities of dissolved gases—oxygen, nitrogen, and carbon dioxid; and sometimes hydrogen sulphid and sulphur dioxid. The absence of carbonates and the presence of nitrates and oxygen render rain-water particularly prone to dissolve lead, when in contact with that metal. In summer, rain-water is liable to become charged with vegetable organic matter suspended in the atmosphere.

*Ice-water* contains very small quantities of dissolved solids or

gases, which, during freezing, remain in great part in the unfrozen water. Suspended impurities are imprisoned in the ice and liberated when this is melted.

*Melted snow* contains about the same proportion of fixed solid matter as rain-water, but a less proportion of ammoniacal salts and of gases.

*Spring water* is rain-water which, having percolated through a portion of the earth's crust (in which it may also have been subjected to pressure), has become charged with solid and gaseous matter: varying in kind and quantity according to the nature of the strata through which it has percolated, the duration of contact, and the pressure to which it was subject during such contact.

Spring-waters from igneous rocks and from the older sedimentary formations are fresh and sweet, and any spring-water may be considered such whose temperature is less than 20° (68° F.), and which does not contain more than 40 parts in 100,000 of solid matter: provided that a large proportion of the solid matter does not consist of salts having a medicinal action, and that sulphurous gases and sulphids are absent.

Artesian wells are artificial springs, produced by boring in a low-lying district, until a pervious layer, between two impervious strata, is reached; the outcrop of the system being in an adjacent elevated region.

*River-water* is a mixture of rain-water, spring-water, and the drainage water of the district through which the river flows, to which snow-water, ice-water, or sea-water is sometimes added. The water of a river flowing rapidly through a granitic region is, unless polluted by man, bright, fresh, and highly aerated. That of a stream flowing sluggishly through rich alluvial land is unaerated, and rich in dissolved and suspended solids.

The amount of dissolved solids in river-water increases with the distance from its source.

The chief sources of pollution of river-water are by the discharge into them of the sewage of towns and cities, or of the waste products of factories.

*Lake-water* is an accumulation of river- and rain-water. As the waters of lakes are kept in constant agitation both by the wind and by the current, they become to a certain extent purified from organic contamination.

*Well-water* may be very good or very bad. If the well be simply a reservoir dug over a spring, and removed from sources of contamination, it has all the characters of fresh spring-water. If, on the other hand, it be simply a hole dug in the earth, the water which it contains is the surface water which has percolated through the thin layer of earth corresponding to the depth of the

well, and is consequently warm, unacrated and charged with organic impurity. Such water is sometimes called "ground water."

Wells dug near dwellings are very liable to become charged with the worst of contaminations, animal excreta, by their filtration through the soil, either by reason of the fracture of the house-drain or otherwise.

**Impurities in Potable Waters.**—A water to be fit for drinking purposes should be cool, limpid, and odorless. It should have an agreeable taste, neither flat, salty, nor sweetish, and it should dissolve soap readily, without formation of any flocculent precipitate.

Although it is safe to condemn a water which does not possess the above characters, it is by no means safe to regard all waters which do possess them as beyond suspicion. To determine whether a water is potable it must be more carefully examined as to the following constituents :

**Total Solids.**—The amount of solid material dissolved in potable waters varies from 5 to 40 in 100,000 ; and a water containing more than the latter quantity is to be condemned on that account alone.

To determine the quantity of total solids 500 c.c. of the filtered water are evaporated to dryness in a previously weighed platinum dish, over the water-bath. The dish with the contained dry residue is cooled in a desiccator and again weighed. The increase in weight, multiplied by 200, gives the total solids in parts per 100,000.

**Hardness.**—The greater part of the solid matter dissolved in natural fresh waters consists of the salts of calcium, accompanied by less quantities of the salts of magnesium. The calcium salt is usually the carbonate or the sulphate ; sometimes the chlorid, phosphate, or nitrate.

A water containing an excess of calcareous salt is said to be **hard**, and one not so charged is said to be **soft**. If the hardness be due to the presence of the carbonate it is **temporary**, if due to the sulphate it is **permanent**. Calcium carbonate is almost insoluble in pure water, but in the presence of free carbonic acid the more soluble bicarbonate is dissolved. But, on the water being boiled, it is decomposed, with precipitation of the carbonate, if the quantity exceed 50 in 100,000. As calcium sulphate is held in solution by virtue of its own, albeit sparing, solubility, it is not deposited when the water is boiled.

An accurate determination of the quantity of calcium and magnesium salts in water is rarely required. It is, however, frequently desirable to determine their quantity approximately, the result being the **degree of hardness**.

For this purpose a solution of soap of known strength is required. This is made by dissolving 10 grains of air dried, white Castile soap, cut into thin shavings, in a litre of dilute alcohol (sp. gr. 0.949). To determine whether this solution contains the proper amount of soap, 10 c.c. of a solution, made by dissolving 1.11 grams of pure, recently fused calcium chlorid in a litre of water, are diluted with 60 c.c. of water and the soap solution added until a persistent lather is produced on agitation. If 11 c.c. of soap solution have been used it has the proper strength; if a greater or less quantity have been added it must be concentrated or diluted in proportion to the excess or deficiency. The soap solution must not be filtered, but, if turbid, must be shaken before using.

To determine the hardness, 70 c.c. of the water to be tested are placed in a glass-stoppered bottle of 250 c.c. capacity, and the soap solution gradually added from a burette. After each addition of soap solution the bottle is shaken, and allowed to lie upon its side five minutes. This is continued until at the end of five minutes a lather remains upon the surface of the liquid in the bottle. At this time the hardness is indicated by the number of c.c. of soap solution added, minus one. If more than 16 c.c. of soap solution are added the liquid in the bottle must be diluted with 70 c.c. of distilled water.

A good drinking-water should not have a hardness of more than fifteen.

**Chlorids.**—The presence of the chlorids of the alkaline metals, in quantities not sufficient to be detectable by the taste, is of no importance *per se*; but in connection with the presence of organic impurity, a determination of the amount of chlorin affords a ready method of indicating the probable source of the organic contamination. As vegetable organic matter brings with it but small quantities of chlorids, while animal contaminations are rich in those compounds, the presence of a large amount of chlorin serves to indicate that organic impurity is of animal origin. Indeed, when time presses, as during an epidemic, it is best to rely upon determinations of chlorin, and condemn all waters containing more than 1.5 in 100,000 of that element.

For the determination of chlorin two solutions are required: a solution of silver nitrate containing 4.79 grams per litre; a strong solution of potassium chromate. One hundred c.c. of the water are placed in a beaker with enough of the chromate solution to communicate a distinct yellow color. If the reaction be acid it is rendered neutral or *faintly* alkaline by the addition of sodium carbonate solution. The silver solution is now allowed to flow in from a burette, drop by drop, during constant agitation, until a *faint* reddish tinge persists. At this time the burette reading is taken; each c.c. of silver solution added represents 0.01 of chlorin per litre.

**Organic Matter.**—The most serious of the probable contaminations of drinking-water is that by organic matters containing nitrogen. When these are present in even moderate quantity, and when, at the same time, the proportion of chlorin is greater

than usual, the water has been contaminated by animal excreta and contains, under suitable conditions, the causes of disease, be they germs or poisons.

Of the methods suggested for the determination of the amount of organic matter in natural waters there is, unfortunately, none which is easy of application and at the same time reliable. That which yields the best results is Wanklyn's process :

The following solutions are required : *a.* Made by dissolving 200 grams of potassium hydrate and 8 grams of potassium permanganate in a litre of water. The solution is boiled down to about 725 c.c., cooled, and brought to its original bulk by the addition of boiled distilled water. *b. Nessler's reagent.* 35 grams of potassium iodid and 13 grams of mercuric chlorid are dissolved in 800 c.c. of water by the aid of heat and agitation. A cold, saturated solution of mercuric chlorid is then added, drop by drop, until the red precipitate which is formed is no longer redissolved on agitation : 160 grams of potassium hydrate are then dissolved in the liquid, to which a slight excess of mercuric chlorid solution is finally added, and the bulk of the whole made up to a litre with water. The solution is allowed to stand, decanted, and preserved in completely filled, well-stoppered bottles. *c. Standard solutions of ammonia.* The stronger of these is made by dissolving 3.15 grams of ammonium chlorid in a litre of water. The weaker, by mixing one volume of the stronger with 99 volumes of water. The latter contains 0.00001 gram of ammonia in each c.c., and is the one used in the determinations, the stronger solution serving only for its convenient preparation. *d. A saturated solution of sodium carbonate.* *e. Distilled water.* The middle third of the distillate, 100 c.c. of which must not be perceptibly colored in ten minutes by the addition of 2 c.c. of Nessler's reagent.

The testing of a water is conducted as follows : Half a litre of the water to be tested (before taking the sample the demijohn or other vessel containing the water must be thoroughly shaken) is introduced, by a funnel, into a tubulated retort capable of holding one litre. If the water be acid, 10 c.c. of the solution of sodium carbonate *d* are added. Having connected the retort with a Liebig's condenser, the joint being made tight by a packing of moistened filter-paper, the water is made to boil as soon as possible by applying the flame of a Bunsen burner brought close to the bottom of the naked retort. The first 50 c.c. of distillate are collected in a cylindrical vessel of clear glass, about an inch in diameter. The following 150 c.c. are collected and thrown away, after which the fire is withdrawn. While these are passing over, the first 50 c.c. are Nesslerized (*vide infra*), and the result, plus one-third as much again, is the amount of free ammonia contained in the half-litre of water.

When 200 c.c. have distilled over, all the free ammonia has been removed, and it now remains to decompose the organic material, and determine the amount of ammonia formed. To effect this, 50 c.c. of the permanganate solution *a* are added through the funnel to the contents of the retort, which is shaken, stoppered, and again heated. The distillate is now collected in separate portions of 50 c.c. each, in glass cylinders, until 3 such portions have been collected. These are then separately Nesslerized as follows : 2 c.c. of the Nessler reagent are added to the

sample of 50 c.c. of distillate; if ammonia be present, a yellow or brown color will be produced, dark in proportion to the quantity of ammonia present. Into another cylinder a given quantity of the standard solution of ammonia *c* is allowed to flow from a burette; enough water is added to make the bulk up to 50 c.c., and then 2 c.c. of Nessler reagent. This cylinder, and that containing the 50 c.c. of Nesslerized distillate, are then placed side by side on a sheet of white paper and their color examined. If the shade of color in the two cylinders be *exactly* the same, the 50 c.c. of distillate contain the same amount of ammonia as the quantity of standard solution of ammonia used. If the colors be different in intensity, another comparison-cylinder must be arranged, using more or less of the standard solution, as the first comparison-cylinder was lighter or darker than the distillate. When the proper similarity of shades has been attained, the number of cubic centimetres of the standard solution used is determined by the reading on the burette. This process, which, with a little practice, is neither difficult nor tedious, is to be repeated with the first 50 c.c. of distillate and with the three portions of 50 c.c. each, distilled after the addition of the permanganate solution. If, for example, it required 1 c.c. of standard solution in Nesslerizing the first 50 c.c., and for the others 3.5 c.c., 1.5 c.c., and 0.2 c.c., the following is the result and the usual method of recording it:

Free ammonia.....	.01
Correction.....	.003
	----
	.013
Free ammonia per litre.....	.026 milligr.
Albuminoid ammonia;.....	.035
	.015
	.002
	----
	.052
Albuminoid ammonia per litre.....	.104 milligr.

If a water yield no albuminoid ammonia it is organically pure, even if it contains much free ammonia and chlorids. If it contain from .02 to .05 milligrams per litre, it is still quite pure. When the albuminoid ammonia reaches 0.1 milligr. per litre the water is to be looked upon with suspicion; and it is to be condemned when the proportion reaches 0.15. When free ammonia is also present in considerable quantity, a water yielding 0.05 of albuminoid ammonia is to be looked upon with suspicion.

**Nitrates and Nitrites**—Are present in rain-water in quantities less than 2 parts in 100,000, calculated as  $N_2O_5$ . When the amount exceeds this, these salts are considered as indicating previous contamination by organic matter which has been oxidized and whose nitrogen has been to some extent converted into nitrites and nitrates.

To determine the amount of nitrous acid the following solutions are used: 1.) Dilute sulphuric acid 1:3; 2.) A solution containing 5 grams of metapheylendiamin and sufficient sulphuric acid to

form an acid reaction in 1 litre of  $H_2O$ ; 3.) A solution made by dissolving 0.406 gram pure, dry silver nitrite in hot water, adding pure sodium chlorid so long as a precipitate is formed, diluting with  $H_2O$  to 1 litre, after cooling and without filtration. 100 c.c. of the clear liquid are then diluted to 1 litre. 1 c.c. of this solution contains 0.01 mgr.  $N_2O_3$ .

To make the determination 100 c.c. of the water are placed in a glass cylinder and 1 c.c. each of solutions 1 and 2 added. Three other cylinders are at the same time prepared, by diluting from 0.3 to 2.5 c.c. of solution 3 to 100 c.c. with pure  $H_2O$ , and adding to each 1 c.c. each of solutions 1 and 2. The shade of color of the water-cylinder is then compared with that of the others, as described above in Nesslerizing. The amount of  $N_2O_3$  in the water is equal to that in the comparison-cylinder having the same shade.

**Poisonous Metals.**—Those most liable to occur in drinking-waters are iron, copper, and lead, and of these the last is the most important.

The power possessed by a water of dissolving lead varies materially with the nature of the substances which it holds in solution. Lead is not dissolved by water as lead, but only after conversion into an oxid; therefore any condition favoring the oxidation of the metal favors its solution. The presence of nitrates is favorable to the solution of lead, an influence which is, however, much diminished by the simultaneous presence of other salts. A water highly charged with oxygen dissolves lead readily, especially if the metallic surface be so exposed to the action of the water as to be alternately acted upon by it and by the air. On the other hand, waters containing carbonates or free carbonic acid may be left in contact with lead with comparative impunity, owing to the formation of a protective coating of the insoluble carbonate of lead on the surface of the metal. This does not apply, however, to water charged with a large excess of carbon dioxid under pressure. Of all natural waters, that most liable to contamination with lead is rain-water. It contains ammonium nitrate with very small quantities of other salts; and it is highly aerated, but contains no carbonates, and comparatively small quantities of carbon dioxid. Obviously, therefore, rain-water should neither be collected from a leaden roof, nor stored in leaden tanks, nor drunk after having been long in contact with lead pipes. As a rule, the purer the water the more liable it is to dissolve lead when brought in contact with that metal, especially if the contact occur when the water is at a high temperature, or when it lasts for a long period.

To determine the power of water for dissolving lead, take two tumblers of the water to be tested; in one place a piece of lead, whose surface has been scraped bright, and allow them to stand twenty four hours. At the end of that time, remove the lead and

pass sulphuretted hydrogen through the water in both tumblers. If the one which contained the metal become perceptibly darker than the other, the water has a power of dissolving lead, such as to render its contact with surfaces of that metal dangerous if prolonged beyond a short time.

To test for the presence of poisonous metals, solution of ammonium sulphhydrate is added to the water, contained in a porcelain capsule. If a dark color be produced, which is not discharged on addition of hydrochloric acid, the water is contaminated with lead or copper.

For quantitative determinations, solutions containing known quantities of the poisonous metals are used: for iron 4.96 grams of ferrous sulphate in a litre of water; for copper 3.93 grams of cupric sulphate to the litre; and for lead 1.66 gram of lead acetate to the litre. One c.c. of each solution contains 0.001 gram of the metal. To use the solutions 100 c.c. of the water to be tested and 100 c.c. of pure water are placed in two porcelain capsules, to each of which some ammonium sulphhydrate is then added. The appropriate standard solution is then allowed to flow into the capsule containing the pure water, until the shade of color produced is the same as that of the liquid in the other capsule. The burette reading at this time gives the number of centigrams of the metal in a litre of water.

**Suspended Solids.**—Most natural waters deposit, on standing, more or less solid, insoluble material. These substances have been either suspended mechanically in the water, which deposits them when it remains at rest, or they have been in solution, and are deposited by becoming insoluble as the water is deprived of carbon dioxide by exposure to air and by relief from pressure.

The suspended particles should be collected by subsidence in a conical glass, and should be examined microscopically for low forms of animal and vegetable life. The quantity of suspended solids is determined by passing a litre of the turbid water through a dried and weighed filter, which, with the collected deposit, is again dried and weighed. The difference between the two weights is the weight of suspended matter in a litre of the water.

**Bacteriological Examination of Water.**—In recent years much attention has been given to the examination of natural waters by bacteriological methods, plate cultures on gelatin, cultures in blood serum and on potatoes, and experiments on animals. Although in some instances pathogenic bacteria have been found in water, and although in the future valuable results will probably be attained by these methods, the chief reliance in determining the quality of a drinking-water is still to be placed upon the older chemical processes.

**Purification of Water.**—The artificial means of rendering a more or less contaminated water fit for use are of five kinds: 1. Distil-

lation; 2. Subsidence; 3. Filtration; 4. Precipitation; 5. Boiling.

The method of **distillation** is used in the laboratory when a very pure water is desired, and also at sea. Distilled water is, however, too pure for continued use, being hard of digestion, and flat to the taste from the absence of gases and of solid matter in solution. When circumstances oblige the use of such water, it should be agitated with air, and should be charged with inorganic matter to the extent of about 0.03 gram each of calcic bicarbonate and sodium chlorid to the litre.

Purification by **subsidence** is adopted only as an adjunct to precipitation and filtration, and for the separation of the heavier particles of suspended matter.

The ideal process of **filtration** consists in the separation of all particles of suspended matter, without any alteration of such substances as are held in solution. In the filtration of potable waters on a large scale, however, the more minute particles of suspended matters are only partially separated, while, on the other hand, an important change in the dissolved materials takes place, at least in certain kinds of filters, in the oxidation of organic matters, whether in solution or in suspension. In the filtration of large quantities of water it is passed through sand or charcoal, or through both substances arranged in alternate layers. Filtration through charcoal is much more effective than that through sand, owing to the much greater activity of the oxidation of nitrogenized organic matter in the former case.

**Precipitation** processes are only adapted to hard waters, and are designed to separate the excess of calcium salt, and at the same time a considerable quantity of organic matter, which is mechanically carried down with the precipitate. The method usually followed consists in the addition of lime (in the form of lime-water), in just sufficient quantity to neutralize the excess of carbon dioxid present in the water. The added lime, together with the calcium salt naturally present in the water, is then precipitated, except that small portion of calcium carbonate which the water, freed from carbon dioxid, is capable of dissolving. To determine when sufficient lime-water has been added, take a sample from time to time during the addition, and test it with solution of silver nitrate until a brown precipitate is formed. At this point cease the addition of lime-water and mix the limed water with further portions of the hard water, until a sample, treated with silver-nitrate solution, gives a yellowish in place of a brown color.

The purification of water by **boiling** can only be carried on upon a small scale. It is, however, of great value for the softening of temporarily hard waters, and for the destruction of organ-

ized impurities, for which latter purpose it should never be neglected during outbreaks of cholera and typhoid, if, indeed, water be drank at all at such times.

**Natural Purification of Water.**—The water of brooks, rivers, and lakes which have been contaminated by sewage and other organic impurity becomes gradually purified by natural processes. Suspended particles are deposited upon the bottom and sides of the stream, more or less rapidly, according to their gravity and the rapidity of the current. The bicarbonates of calcium, magnesium, and iron gradually lose carbon dioxide, and are precipitated as carbonates, which mechanically carry down dissolved as well as suspended impurities. The fermentations, oxidations, and reductions to which organic matters are subject bring about their gradual mineralization and the conversion of ammonia into nitrates. The processes of nutrition of aquatic plant life absorb dissolved organic impurity, as well as the products of decomposition of nitrogenized substances. This natural purification proceeds the more rapidly the more contact with air is favored.

**Mineral Waters.**—Under this head are classed all waters which are of therapeutic or industrial value, by reason of the quantity or nature of the dissolved solids which they contain: or which have a temperature greater than 20° (68° F.).

The composition of mineral waters varies greatly, according to the nature of the strata or veins through which the water passes, and to the conditions of pressure and previous composition under which it is in contact with these deposits.

The substances almost universally present in mineral waters are: oxygen, nitrogen, carbon dioxide; sodium carbonate, bicarbonate, sulphate and chlorid; and calcium bicarbonate. Of substances occasionally present the most important are: sulphydric acid; sulphids of sodium, iron, and magnesium; bromids and iodids of sodium and magnesium; calcium and magnesium chlorids; carbonate, bicarbonate, sulphate, peroxid, and crenate of iron; silicates of sodium, calcium, magnesium, and iron; aluminium salts; salts of lithium, cesium, and rubidium; free sulphuric, silicic, arsenic, and boric acids; and ammoniacal salts.

Although a sharply defined classification of mineral waters is not possible, one which is useful, if not accurate, may be made, based upon the predominance of some constituent, or constituents, which impart to the water a well-defined therapeutic value. A classification which has been generally adopted includes five classes:

1. *Acidulous waters*; whose value depends upon dissolved carbonic acid. They contain but small quantities of solids, principally the bicarbonates of sodium and calcium and sodium chlorid.

II. *Alkaline waters*; which contain notable quantities of the carbonates or bicarbonates of sodium, potassium, lithium, and calcium, sufficient to communicate to them an alkaline reaction, and frequently a soapy taste; either naturally, or after expulsion of carbon dioxid by boiling.

III. *Chalybeate waters*; which contain salts of iron in greater proportion than 4 parts in 100,000. They contain ferrous bicarbonate, sulphate, crenate, and apocrenate, calcium carbonate, sulphates of potassium, sodium, calcium, magnesium, and aluminium, notable quantities of sodium chlorid, and frequently small amounts of arsenic. They have the taste of iron and are usually clear as they emerge from the earth. Those containing ferrous bicarbonate deposit a sediment on standing, by loss of carbon dioxid, and formation of ferrous carbonate.

IV. *Saline waters*; which contain neutral salts in considerable quantity. The nature of the salts which they contain is so diverse that the group may well be subdivided:

*a. Chlorin waters*; which contain large quantities of sodium chlorid, accompanied by less amounts of the chlorids of potassium, calcium, and magnesium. Some are so rich in sodium chlorid that they are not of service as therapeutic agents, but are evaporated to yield a more or less pure salt. Any natural water containing more than 300 parts in 100,000 of sodium chlorid belongs to this class, provided it do not contain substances more active in their medicinal action in such proportion as to warrant its classification elsewhere. Waters containing more than 1,500 parts in 100,000 are too concentrated for internal administration.

*β. Sulphate waters* are actively purgative from the presence of considerable proportions of the sulphates of sodium, calcium, and magnesium. Some contain large quantities of sodium sulphate, with mere traces of the calcium and magnesium salts, while in others the proportion of the sulphates of magnesium and calcium is as high as 3,000 parts in 100,000 to 2,000 parts in 100,000 of sodium sulphate. They vary much in concentration; from 500 to nearly 6,000 parts of total solids in 100,000. They have a salty, bitter taste, and vary much in temperature.

*γ. Bromin and iodin waters* are such as contain the bromids or iodids of potassium, sodium, or magnesium in sufficient quantity to communicate to them the medicinal properties of those salts.

V. *Sulphurous waters*; which hold hydrogen sulphid or metallic sulphids in solution. They have a disagreeable odor and are usually warm. They contain 20 to 400 parts in 100,000 of total solids.

**Physiological.**—Water is taken into the body both as a liquid and as a constituent of every article of food; the amount ingested by a healthy adult being 2.25 to 2.75 litres (2½ to 3 quarts) per

dium. The greater the elimination and the drier the nature of the food the greater is the amount of  $H_2O$  taken in the liquid form.

Water is a constituent of every tissue and fluid of the body, varying from 0.2 per cent. in the enamel of the teeth to 99.5 per cent. in the perspiration and saliva. It constitutes about 60 per cent. of the weight of the body.

The consistency of the various parts does not depend entirely upon the relative proportion of solids and  $H_2O$ , but is influenced by the nature of the solids. The blood, although liquid in the ordinary sense of the term, contains a less proportional amount of  $H_2O$  than does the tissue of the kidneys, and about the same proportion as the tissue of the heart. Although the bile and mucus are not as fluid as the blood, they contain a larger proportion of  $H_2O$  to solids than does that liquid.

Water is discharged by the kidneys, intestine, skin, and pulmonary surfaces. The quantity discharged is greater than that ingested; the excess being formed in the body by the oxidation of the H of its organic constituents.

### Hydrogen Dioxid.

#### *Hydrogen peroxid—Oxygenated water.*

$H_2O_2$ —*Molecular weight* = 34—*Sp. gr.* = 1.455—*Discovered by Thénard in 1818.*

Exists naturally in very minute quantity in rain-water, in air, and in the saliva.

This substance may be obtained in a state of purity by accurately following the process of Thénard. It may also be obtained, mixed with a large quantity of  $H_2O$ , by passing a rapid current of carbon dioxid through  $H_2O$  holding hydrate of barium dioxid in suspension— $BaO_3H_2 + CO_2 = BaCO_3 + H_2O_2$ . It is also formed in small quantity during the slow oxidation of many elements and compounds, such as P, Pb, Zn, Cd, Al, alcohol, ether, and the essences.

It is prepared industrially of 10–12 volume strength by gradually adding barium peroxid to dilute hydrofluoric acid solution, the mixture being maintained at a low temperature and constantly agitated.

The pure substance is a colorless, syrupy liquid, which, when poured into  $H_2O$ , sinks under it before mixing. It has a disagreeable, metallic taste, somewhat resembling that of tartar emetic. When taken into the mouth it produces a tingling sensation, increases the flow of saliva, and bleaches the tissues with which it comes in contact. It is still liquid at  $-30^\circ$  ( $-22^\circ$  F.). It is very unstable, and, even in darkness and at ordinary temperature, is gradually decomposed. At  $20^\circ$  ( $68^\circ$  F.) the decomposition takes

place more quickly, and at 100° (212° F.) rapidly and with effervescence. The dilute substance, however, is comparatively stable, and may be boiled and even distilled without suffering decomposition. Yet it is liable to explosive decomposition when exposed to summer temperature in closed vessels.

Hydrogen peroxid acts both as a reducing and an oxidizing agent. Arsenic, sulphids, and sulphur dioxid are oxidized by it at the expense of half its oxygen. When it is brought in contact with silver oxid both substances are violently decomposed, water and elementary silver remaining. By certain substances, such as gold, platinum, and charcoal in a state of fine division, fibrin, or manganese dioxid, it is decomposed with evolution of oxygen: the decomposing agent remaining unchanged.

The pure substance, when decomposed, yields 475 times its volume of oxygen; the dilute 15 to 20 volumes.

In dilute solution it is used as a bleaching agent and in the renovation of old oil-paintings. It is an energetic disinfectant and antiseptic, and is extensively used in surgery.

**Analytical Characters.**—1. To a solution of starch a few drops of cadmium iodid solution are added, then a small quantity of the fluid to be tested, and, finally, a drop of a solution of ferrous sulphate. A blue color is produced in the presence of hydrogen peroxid, even if the solution contain only 0.05 milligram per litre.

2. Add freshly prepared tincture of guaiacum and a few drops of a cold infusion of malt. A blue color—1 in 2,000,000.

3. Add the liquid to be tested to mixed solutions of ferric chlorid and potassium ferrieyanid (which should have no blue tinge). A blue color—1 in 10,000,000.

4. Add to 6 c.c. of the liquid sulphuric acid, iodid of zinc, starch-paste, two drops of a two per cent. solution of cupric sulphate, and a little one-half per cent. solution of ferrous sulphate, in the order named. A blue color.

5. Add a trace of acetic acid, some  $\alpha$  naphthylamin and solid sodium chlorid. After a short time a blue or blue-violet color and, after some hours, a flocculent ppt. of the same color.

**Atmospheric Hydrogen Dioxid.**—It has been claimed that atmospheric air, rain-water, snow, and hoar-frost constantly contain small quantities of hydrogen peroxid; the amount in rain-water varying from 0.0008 to 0.05 part in 100,000. The most recent experiments bearing upon the supposed presence of ozone and hydrogen peroxid in atmospheric air seem, however, to justify the belief that those substances, if present in air at all, are not met with in the amounts and with the constancy that have been claimed. According to this later view, the appearances from which the presence of ozone and hydrogen peroxid has been inferred are not caused by those substances, but by nitrous acid and the oxids of nitrogen.

## CLASS II.—ACIDULOUS ELEMENTS.

Elements all of whose Hydrates are Acids, and which do not form Salts with the Oxacids.

## I. CHLORIN GROUP.

FLUORIN. CHLORIN. BROMIN. IODIN.

The elements of this group are univalent. With hydrogen they form acid compounds, composed of one volume of the element in the gaseous state with one volume of hydrogen. Their hydrates are monobasic acids when they exist (fluorin forms no hydrate). The first two are gases, the third liquid, the fourth solid at ordinary temperatures. They are known as the **halogens**. The relations of their compounds to each other are shown in the following table :

HF	—	—	—	—	—	—	—
HCl	Cl <sub>2</sub> O	Cl <sub>2</sub> O <sub>3</sub>	Cl <sub>2</sub> O <sub>4</sub>	HClO	HClO <sub>2</sub>	HClO <sub>3</sub>	HClO <sub>4</sub>
HBr	—	—	—	HBrO	—	HBrO <sub>3</sub>	HBrO <sub>4</sub>
HI	—	—	I <sub>2</sub> O <sub>4</sub>	HIO	HIO <sub>2</sub>	HIO <sub>3</sub>	HIO <sub>4</sub>
Hydro-fluoric acid.	Monoxid.	Trioxid.	Tetroxid.	Hypo-ous acid.	-ous acid.	-ic acid.	Per-ic acid.

## FLUORIN.

*Symbol* = **F**—*Atomic weight* = 19—*Sp. gr.* 1.265 *A* (*calculated* = 1.316)—*Discovered by Sir H. Davy in 1812.*

Fluorin has been isolated by the electrolysis of HF at  $-23^{\circ}$  ( $-9^{\circ}.4$  F.).

It is a gas, colorless in thin layers, greenish-yellow in layers 50 cent. thick.

It decomposes H<sub>2</sub>O, with formation of HF and ozone. In it Si, Bo, As, Sb, S, and I fire spontaneously. With H it detonates violently, even in the dark. It attacks organic substances violently. The apparatus in which it is liberated must be made of platinum and fluor-spar. It forms compounds with all other elements except oxygen.

**Hydrogen Fluorid**—*Hydrofluoric acid* = **HF**—*Molecular weight* = 20. Hydrofluoric acid is obtained by the action of an excess of sulphuric acid upon fluor-spar or upon barium fluorid, with the aid of gentle heat :  $\text{CaF}_2 + \text{H}_2\text{SO}_4 = \text{CaSO}_4 + 2 \text{HF}$ . If a solution be desired, the operation is conducted in a platinum or lead retort, whose beak is connected with a U-shaped receiver of the same metal, which is cooled and contains a small quantity of water.

The aqueous acid is a colorless liquid, highly acid and corro-

sive, and having a penetrating odor. Great care must be exercised that neither the solution nor the gas come in contact with the skin, as they produce painful ulcers which heal with difficulty, and also constitutional symptoms which may last for days. The inhalation of air containing very small quantities of HF has caused permanent loss of voice and, in two cases, death. When the acid has accidentally come in contact with the skin the part should be washed with dilute solution of potash, and the vesicle which forms should be opened.

Both the gaseous acid and its solution remove the silica from glass, a property utilized in etching upon that substance, the parts upon which no action is desired being protected by a coating of wax.

The presence of fluorin in a compound is detected by reducing the substance to powder, moistening it with sulphuric acid in a platinum crucible, over which is placed a slip of glass prepared as above; at the end of half an hour the wax is removed from the glass, which will be found to be etched if the substance examined contained a fluorid.

### CHLORIN.

*Symbol = Cl—Atomic weight = 35.5—Molecular weight = 71—Sp. gr. = 2.4502 A—One litre weighs 3.17 grams—100 cubic inches weigh 76.3 grains—Name derived from χλωρός = yellowish-green—Discovered by Scheele in 1774.*

**Occurrence.**—Only in combination, most abundantly in sodium chlorid.

**Preparation.**—(1.) By heating together manganese dioxid and hydrochloric acid (Scheele). The reaction takes place in two stages. Manganic chlorid is first formed according to the equation:  $\text{MnO}_2 + 4\text{HCl} = \text{MnCl}_4 + 2\text{H}_2\text{O}$ ; and is subsequently decomposed into manganous chlorid and chlorin:  $\text{MnCl}_4 = \text{MnCl}_2 + \text{Cl}_2$ .

This and similar operations are usually conducted in an apparatus such as that shown in Fig. 23. The earthenware vessel A (which on a small scale may be replaced by a glass flask) is two-thirds filled with lumps of manganese dioxid of the size of hazelnuts, and adjusted in the water-bath; hydrochloric acid is poured in through the safety-tube and the bath heated. The disengaged gas is caused to bubble through the small quantity of water in B, is then dried by passage over the fragments of calcium chlorid in C, and is finally collected by displacement of air in the vessel D.

When the vessel A has become half filled with liquid it is best to decant the solution of manganous chlorid, wash the remaining oxid with water and begin anew. A kilo. of oxid yields 257.5 litres of Cl.

(2.) By the action of manganese dioxid upon hydrochloric acid in the presence of sulphuric acid, manganous sulphate being also formed:  $\text{MnO}_2 + 2\text{HCl} + \text{H}_2\text{SO}_4 = \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2$ . The same quantity of chlorin is obtained as in (1), with the use of half the amount of hydrochloric acid.

(3.) By heating a mixture of one part each of manganese dioxid and sodium chlorid, with three parts of sulphuric acid. Hydrochloric acid and sodium sulphate are first formed:  $\text{H}_2\text{SO}_4 + 2\text{NaCl} = \text{Na}_2\text{SO}_4 + 2\text{HCl}$ ; and the acid is immediately decomposed by either of the reactions indicated in (1) and (2), according as sulphuric acid is or is not present in excess.

(4.) By the action of potassium dichromate upon hydrochloric

FIG. 23.

acid; potassium and chromic chlorids being also formed:  $\text{K}_2\text{Cr}_2\text{O}_7 + 14\text{HCl} = 2\text{KCl} + \text{Cr}_2\text{Cl}_6 + 7\text{H}_2\text{O} + 3\text{Cl}_2$ . Two parts of powdered dichromate are heated with 17 parts of acid of sp. gr. 1.16; 100 grams of the salt yielding 22.5 litres of  $\text{Cl}$ .

(5.) A convenient method of obtaining chlorin on a laboratory scale is by the use of "chlorin cubes." These are made by pressing together 1 part of plaster of Paris and 4 parts of chlorid of lime (q. v.), cutting into small cubes and drying. The cubes are used in one of the forms of constant apparatus (Figs. 19, 20, 21), with dilute hydrochloric acid,  $\text{Cl}$  being evolved at the ordinary temperature.

When a slow evolution of  $\text{Cl}$ , extending over a considerable

period of time, is desired, as for ordinary disinfection, moistened chlorid of lime is exposed to the air, the calcium hypochlorite being decomposed by the atmospheric carbon dioxid. If a more rapid evolution of gas be desired, the chlorid of lime is moistened with dilute hydrochloric acid in place of with water.

(6.) By the action of potassium chlorate upon hydrochloric acid Cl is liberated, slowly at the ordinary temperature, more rapidly at the temperature of the water-bath :

**Properties.**—*Physical.*—A greenish-yellow gas, at the ordinary temperature and pressure ; it has a penetrating odor, and is, even when highly diluted, very irritating to the respiratory passages. Being soluble in  $\text{H}_2\text{O}$  to the extent of one volume to three volumes of the solvent, it must be collected by displacement of air, as shown in Fig. 23. A saturated aqueous solution of Cl is known to chemists as **chlorin water**, and in pharmacy as **aqua chlori** (*U. S.*), **Liquor chlori** (*Br.*). It should bleach, but not redden, litmus paper. Under a pressure of 6 atmospheres at  $0^\circ$  ( $32^\circ \text{F.}$ ), or  $8\frac{1}{2}$  atmospheres at  $12^\circ$  ( $53.6^\circ \text{F.}$ ), Cl becomes an oily, yellow liquid, of sp. gr. 1.33 ; and boiling at  $-33.6^\circ$  ( $-28^\circ.5 \text{F.}$ ).

*Chemical.*—Chlorin exhibits a great tendency to combine with other elements, with all of which, except F, O, N, and C, it unites directly, frequently with evolution of light as well as heat, and sometimes with an explosion. With H it combines slowly, to form hydrochloric acid, under the influence of diffuse daylight, and violently in direct sunlight, or in highly actinic artificial lights. A candle burns in Cl with a faint flame and thick smoke, its H combining with the Cl, while carbon becomes free.

At a red heat Cl decomposes  $\text{H}_2\text{O}$  rapidly, with formation of hydrochloric, chloric, and probably hypochlorous acids. The same change takes place slowly under the influence of sunlight, hence chlorin water should be kept in the dark or in bottles of yellow glass.

In the presence of  $\text{H}_2\text{O}$ , chlorin is an active bleaching and disinfecting agent. It acts as an indirect oxidant, decomposing  $\text{H}_2\text{O}$ , the nascent O from which then attacks the coloring or odorous principle.

Chlorin is readily fixed by many organic substances, either by addition or substitution. In the first instance, as when Cl and olefiant gas unite to form ethylene chlorid, the organic substance simply takes up one or more atoms of chlorin :  $\text{C}_2\text{H}_4 + \text{Cl}_2 = \text{C}_2\text{H}_4\text{Cl}_2$ . In the second instance, as when Cl acts upon marsh gas to produce methyl chlorid :  $\text{CH}_4 + \text{Cl}_2 = \text{CH}_3\text{Cl} + \text{HCl}$ , each

substituted atom of Cl displaces an atom of H, which combines with another Cl atom to form hydrochloric acid.

*Hydrate of chlorin*,  $\text{Cl } 5\text{H}_2\text{O}$ , is a yellowish-green, crystalline substance, formed when Cl is passed through chlorin water, cooled to  $0^\circ$  ( $32^\circ \text{ F.}$ ). It is decomposed at  $10^\circ$  ( $50^\circ \text{ F.}$ ).

**Hydrogen Chlorid—Hydrochloric Acid—Muriatic Acid—Acidum Hydrochloricum** (U. S.; Br.,—**HCl**—*Molecular weight* = 36.5—*Sp. gr.* 1.259 *A—A litre weighs* 1.6293 gram.

**Occurrence.**—In volcanic gases and in the gastric juice of the mammalia.

**Preparation.**—(1.) By the direct union of its constituent elements.

(2.) By the action of sulphuric acid upon a chlorid, a sulphate being at the same time formed:  $\text{H}_2\text{SO}_4 + 2\text{NaCl} = \text{Na}_2\text{SO}_4 + 2\text{HCl}$ .

This is the reaction by which the HCl used in the arts is produced.

(3.) Hydrochloric acid is also formed in a great number of reactions, as when Cl is substituted in an organic compound.

**Properties.**—*Physical.*—A colorless gas, acid in reaction and taste, having a sharp, penetrating odor, and producing great irritation when inhaled. It becomes liquid under a pressure of 40 atmospheres at  $4^\circ$  ( $29^\circ \text{ F.}$ ). It is very soluble in  $\text{H}_2\text{O}$ , one volume of which dissolves 480 volumes of the gas at  $0^\circ$  ( $32^\circ \text{ F.}$ ).

*Chemical.*—Hydrochloric acid is neither combustible nor a supporter of combustion, although certain elements, such as K and Na, burn in it. It forms white clouds on contact with moist air.

**Solution of Hydrochloric Acid.**—It is in the form of aqueous solution that this acid is usually employed in the arts and in pharmacy. It is, when pure, a colorless liquid (yellow when impure), acid in taste and reaction, whose sp. gr. and boiling-point vary with the degree of concentration. When heated, it evolves HCl, if it contain more than 20 per cent. of that gas, and  $\text{H}_2\text{O}$  if it contain less. A solution containing 20 per cent. boils at  $111^\circ$  ( $232^\circ \text{ F.}$ ), is of sp. gr. 1.099, has the composition  $\text{HCl} + 8\text{H}_2\text{O}$ , and distils unchanged.

*Commercial muriatic acid* is a yellow liquid; sp. gr. about 1.16; contains 32 per cent. HCl; and contains ferric chlorid, sodium chlorid, and arsenical compounds.

*Acidum hydrochloricum* is a colorless liquid, containing small quantities of impurities. It contains 31.9 per cent. HCl and its sp. gr. is 1.16 (U. S.; Br.). The dilute acid is the above diluted with water. Sp. gr. 1.049 = 10 per cent. HCl (U. S.); sp. gr. 1.052 = 10.5 per cent. HCl (Br.).

*C. P. (chemically pure) acid* is usually the same as the strong pharmaceutical acid and far from pure (see below).

Hydrochloric acid is classed, along with nitric and sulphuric acids, as one of the three **strong mineral acids**. It is decomposed by many elements, with formation of a chlorid and liberation of hydrogen:  $2\text{HCl} + \text{Zn} = \text{ZnCl}_2 + \text{H}_2$ . With oxids and hydrates of elements of the third and fourth classes it enters into double decomposition, forming  $\text{H}_2\text{O}$  and a chlorid:  $\text{CaO} + 2\text{HCl} = \text{CaCl}_2 + \text{H}_2\text{O}$  or  $\text{CaH}_2\text{O}_2 + 2\text{HCl} = \text{CaCl}_2 + 2\text{H}_2\text{O}$ .

Oxidizing agents decompose  $\text{HCl}$  with liberation of  $\text{Cl}$ . A mixture of hydrochloric and nitric acids in the proportion of three molecules of the former to one of the latter, is the **acidum nitrohydrochloricum** (*U. S.*; *Br.*), or **aqua regia**. The latter name alludes to its power of dissolving gold, by combination of the nascent  $\text{Cl}$ , which it liberates, with that metal, to form the soluble auric chlorid.

**Impurities.**—A chemically pure solution of this acid is exceedingly rare. The impurities usually present are: *Sulphurous acid*—hydrogen sulphid is given off when the acid is poured upon zinc; *Sulphuric acid*—a white precipitate is formed with barium chlorid; *Chlorin* colors the acid yellow; *Lead* gives a black color when the acid is treated with hydrogen sulphid; *Iron*—the acid gives a red color with ammonium sulphocyanate; *Arsenic*—the method of testing by hydrogen sulphid is not sufficient. If the acid is to be used for toxicological analysis, a litre, diluted with half as much  $\text{H}_2\text{O}$ , and to which a small quantity of potassium chlorate has been added, is evaporated over the water-bath to 400 c.c.; 25 c.c. of sulphuric acid are then added, and the evaporation continued until the liquid measures about 100 c.c. This is introduced into a Marsh apparatus and must produce *no* mirror during an hour.

**Chlorids.**—A few of the chlorids are liquid,  $\text{SnCl}_4$ ,  $\text{SbCl}_5$ ; the remainder are solid, crystalline and more or less volatile. The metallic chlorids are soluble in water, except  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , which are insoluble, and  $\text{PbCl}_2$ , which is sparingly soluble. The chlorids of the non-metals are decomposed by  $\text{H}_2\text{O}$ .

The chlorids are formed: 1.) By the direct union of the elements:  $\text{P} + \text{Cl}_5 = \text{PCl}_5$ ; 2.) By the action of chlorin upon a heated mixture of oxid and carbon:  $\text{Al}_2\text{O}_3 + 3\text{C} + 3\text{Cl}_2 = \text{Al}_2\text{Cl}_6 + 3\text{CO}$ ; 3.) By solution of the metal, oxid, hydrate, or carbonate in  $\text{HCl}$ :  $\text{Zn} + 2\text{HCl} = \text{ZnCl}_2 + \text{H}_2$ ; 4.) By double decomposition between a solution of a chlorid and that of another salt whose metal forms an insoluble chlorid:  $\text{AgNO}_3 + \text{NaCl} = \text{AgCl} + \text{NaNO}_3$ .

**Analytical Characters.**—1.) With  $\text{AgNO}_3$  a white, flocculent ppt., insoluble in  $\text{HNO}_3$ , soluble in  $\text{NH}_4\text{HO}$ . 2.) With  $\text{Hg}_2(\text{NO}_3)_2$ , a white ppt., which turns black with  $\text{NH}_4\text{HO}$ .

**Toxicology.—Poisons and corrosives.**—A poison is any substance which, after entrance into the blood, produces death or serious bodily harm.

A corrosive is a substance capable of producing death by its chemical action upon a tissue with which it comes in direct contact, without absorption by the blood.

The corrosives act much more energetically when concentrated than when dilute; and when the dilution is great they have no deleterious action. The degree of concentration in which the true poisons are taken is of little influence upon their action if the dose taken remain the same.

Under the above definitions the strong mineral acids act as corrosives rather than as poisons. They produce their injurious results by destroying the tissues with which they come in contact, and will cause death as surely by destroying a large surface of skin, as when they are taken into the stomach.

The symptoms of corrosion by the mineral acids begin immediately, during the act of swallowing. The chemical action of the acid upon every part with which it comes in contact causes acute burning pain, extending from the mouth to the stomach and intestine, referred chiefly to the epigastrium. Violent and distressing vomiting of dark, tarry, or "coffee-ground," highly acid material is a prominent symptom. Eschars, at first white or gray, later brown or black, are formed where the acid has come in contact with the skin or mucous membrane. Respiration is labored and painful, partly by pressure of the abdominal muscles, but also, in the case of hydrochloric acid, from entrance of the irritating acid gas into the respiratory passages. Death may occur within 24 hours, from collapse; more suddenly from perforation of large blood-vessels, or from peritonitis; or after several weeks, secondarily, from starvation, due to closure of the pylorus by inflammatory thickening, and destruction of the gastric glands.

The object of the treatment in corrosion by the mineral acids is to neutralize the acid and convert it into a harmless salt. For this purpose the best agent is magnesia (magnesia usta), suspended in a small quantity of water, or if this be not at hand, a strong solution of soap. Chalk and the carbonates and bicarbonates of sodium and potassium should not be given, as they generate large volumes of gas. The scrapings of a plastered wall, or oil, are entirely useless. The stomach-pump, or any attempt at the introduction of a tube into the œsophagus, is not to be thought of.

**Compounds of Chlorin and Oxygen.**—Three compounds of chlorin and oxygen have been isolated, two being anhydrides. They are

all very unstable, and prone to sudden and violent decomposition.

**Chlorin Monoxid.**— $\text{Cl}_2\text{O}$ —87—*Hypochlorous anhydrid* or *oxid*, is formed by the action, below  $20^\circ$  ( $68^\circ \text{ F.}$ ), of dry  $\text{Cl}$  upon precipitated mercuric oxid:  $\text{HgO} + 2\text{Cl}_2 = \text{HgCl}_2 + \text{Cl}_2\text{O}$ .

On contact with  $\text{H}_2\text{O}$  it forms **hypochlorous acid**,  $\text{HClO}$ , which, owing to its instability, is not used industrially, although the hypochlorites of  $\text{Ca}$ ,  $\text{K}$ , and  $\text{Na}$  are.

**Chlorin Trioxid**—*Chlorous anhydrid* or *oxid*,  $\text{Cl}_2\text{O}_3$ —119—is a yellowish-green gas formed by the action of dilute nitric acid upon potassium chlorate in the presence of arsenic trioxid. At  $50^\circ$  ( $122^\circ \text{ F.}$ ) it explodes. It is a strong bleaching agent: is very irritating when inhaled and readily soluble in  $\text{H}_2\text{O}$ , the solution probably containing **chlorous acid**,  $\text{HClO}_2$ .

**Chlorin Tetroxid**—*Chlorin peroxid*,  $\text{Cl}_2\text{O}_4$ —135—is a violently explosive body, produced by the action of sulphuric acid upon potassium chlorate. Below  $-20^\circ$  ( $-4^\circ \text{ F.}$ ) it is an orange-colored liquid; above that temperature a yellow gas. It explodes violently when heated to a temperature below  $100^\circ$  ( $212^\circ \text{ F.}$ ). There is no corresponding hydrate known, and if it be brought in contact with an alkaline hydrate, a mixture of chlorate and chlorite is formed.

Besides the above, two oxacids of  $\text{Cl}$  are known, the anhydrids corresponding to which have not been isolated.

**Chloric Acid**— $\text{HClO}_3$ —84.5—obtained, in aqueous solution, as a strongly acid, yellowish, syrupy liquid, by decomposing its barium salt by the proper quantity of sulphuric acid.

**Perchloric Acid**— $\text{HClO}_4$ —100.5—is the most stable of the series. It is obtained by boiling potassium chlorate with hydrofluosilicic acid, decanting the cold fluid, evaporating until white fumes appear, decanting from time to time, and finally distilling. It is a colorless, oily liquid: sp. gr. 1.782; which explodes on contact with organic substances or charcoal.

## BROMIN.

**Bromum, U.S., Br.**—*Symbol* =  $\text{Br}$ —*Atomic weight* = 80—*Molecular weight* = 160—*Sp. gr. of liquid* = 3.1872 at  $0^\circ$ : *of vapor* = 5.52 *A*—*Freezing-point* =  $-24.5^\circ$  ( $-12.1^\circ \text{ F.}$ )—*Boiling-point* =  $63^\circ$  ( $145.4^\circ \text{ F.}$ )—*Name derived from*  $\beta\rho\mu\omega\varsigma$  = *a stench*—*Discovered by Balard in 1826.*

**Occurrence.**—Only in combination, most abundantly with  $\text{Na}$  and  $\text{Mg}$  in sea-water and the waters of mineral springs.

**Preparation.**—It is obtained from the mother liquors, left by the evaporation of sea-water, and of that of certain mineral springs, and from sea-weed. These are mixed with sulphuric

acid and manganese dioxid and heated, when the bromids are decomposed by the Cl produced, and Br distils.

**Properties.**—*Physical.*—A dark reddish-brown liquid, volatile at all temperatures above  $-24.5$  ( $-12.1$  F.); giving off brown-red vapors which produce great irritation when inhaled. Soluble in water to the extent of 3.2 parts per 100 at  $15$  ( $59$  F.); more soluble in alcohol, carbon disulphid, chloroform, and ether.

*Chemical.*—The chemical characters of Br are similar to those of Cl, but less active. With  $H_2O$  it forms a crystalline hydrate at  $0$  ( $32$  F.):  $Br \cdot 5H_2O$ . Its aqueous solution is decomposed by exposure to light, with formation of hydrobromic acid.

It is highly poisonous.

**Hydrogen Bromid—Hydrobromic acid—Acidum hydrobromicum dil. (U. S.) = HBr**—*Molecular weight* = 81—*Sp. gr.* = 2.71 *A*—*A litre weighs* 3.63 grams—*Liquefies* at  $-69$  ( $-92.2$  F.)—*Solidifies* at  $-73$  ( $-99.4$  F.).

**Preparation.**—This substance cannot be obtained from a bromid as HCl is obtained from a chlorid. It is produced, along with phosphorous acid, by the action of  $H_2O$  upon phosphorus tribromid:  $PBr_3 + 3H_2O = H_3PO_3 + 3HBr$ ; or by the action of Br upon paraffin.

**Properties.**—A colorless gas; produces white fumes with moist air; acid in taste and reaction, and readily soluble in  $H_2O$ , with which it forms a hydrate,  $HBr \cdot 2H_2O$ . Its chemical properties are similar to those of HCl.

**Bromids** closely resemble the chlorids and are formed under similar conditions. They are decomposed by chlorin, with formation of a chlorid and liberation of Br:  $2KBr + Cl_2 = 2KCl + Br_2$ . The metallic bromids are soluble in  $H_2O$ , except  $AgBr$  and  $Hg_2Br_2$ , which are insoluble, and  $PbBr_2$ , which is sparingly soluble. The bromids of Mg, Al, Ca are decomposed into oxid and HBr on evaporation of their aqueous solutions.

**Analytical Characters.**—(1.) With  $AgNO_3$ , a yellowish-white ppt., insoluble in  $HNO_3$ , sparingly soluble in  $NH_4HO$ . (2.) With chlorin water a yellow solution which communicates the same color to chloroform and to starch-paste. (3.) With palladic nitrate a black ppt. in the absence of chlorids.

**Oxacids of Bromin.**—No oxids of bromin are known, although three oxacids exist, either in the free state or as salts:

**Hypobromous Acid—HBrO**—97—is obtained, in aqueous solution, by the action of Br upon mercuric oxid, silver oxid, or silver nitrate. When Br is added to concentrated solution of potassium hydrate no hypobromite is formed, but a mixture of bromate and bromid, having no decolorizing action. With sodium hy-

drate, however, sodium hypobromite is formed in solution : and such a solution, freshly prepared, is used in Knop's process for determining urea (q. v.).

**Bromic Acid**— $\text{HBrO}_3$ —129—has only been obtained in aqueous solution, or in combination. It is formed by decomposing barium bromate with an equivalent quantity of sulphuric acid :  $\text{Ba}(\text{BrO}_3)_2 + \text{H}_2\text{SO}_4 = 2\text{HBrO}_3 + \text{BaSO}_4$ . In combination it is produced, along with the bromid, by the action of Br on caustic potassa :  $3\text{Br}_2 + 6\text{KHO} = \text{KBrO}_3 + 5\text{KBr} + 3\text{H}_2\text{O}$ .

**Perbromic Acid**— $\text{HBrO}_4$ —145—is obtained on a comparatively stable, oily liquid, by the decomposition of perchloric acid by Br, and concentrating over the water-bath.

It is noticeable in this connection that, while HCl and the chlorids are more stable than the corresponding Br compounds, the oxygen compounds of Br are more permanent than those of Cl.

## IODIN.

**Iodum (U. S. ; Br.)**—*Symbol* = I—*Atomic weight* = 127—*Molecular weight* = 254—*Sp. gr. of solid* = 4.948 ; *of vapor* = 8.716 *A*—*Fuses at* 113°.6 (236°.5 *F.*)—*Boils at* 175° (347° *F.*)—*Name derived from* *ἰώδης* = violet—*Discovered by* Courtois in 1811.

**Occurrence.**—In combination with Na, K, Ca, and Mg, in seawater, the waters of mineral springs, marine plants and animals. Cod-liver oil contains about 37 parts in 100,000.

**Preparation.**—It is obtained from the ashes of sea-weed, called *kelp* or *varech*. These are extracted with  $\text{H}_2\text{O}$ , and the solution evaporated to small bulk. The mother liquor, separated from the other salts which crystallize out, contains the iodids, which are decomposed by Cl, aided by heat, and the liberated iodin condensed.

**Properties.**—*Physical.*—Blue-gray, crystalline scales, having a metallic lustre. Volatile at all temperatures, the vapor having a violet color, and a peculiar odor. It is sparingly soluble in  $\text{H}_2\text{O}$ , which, however, dissolves larger quantities on standing over an excess of iodin, by reason of the formation of hydriodic acid. The presence of certain salts, notably potassium iodid, increases the solvent power of  $\text{H}_2\text{O}$  for iodin. The **Liq. Iodi Comp.** (*U. S.*), **Liq. Iodi, Br.** is solution of potassium iodid containing free iodin. Very soluble in alcohol ; **Tinct. iodi** (*U. S.* ; *Br.*) ; in ether, chloroform, benzol, and carbon disulphid. With the three last-named solvents it forms violet solutions, with the others brown solutions.

*Chemical.*—In its chemical characters I resembles Cl and Br, but is less active. It decomposes  $\text{H}_2\text{O}$  slowly, and is a weak bleaching and oxidizing agent. It decomposes hydrogen sulphid

with formation of hydriodic acid, and liberation of sulphur. It does not combine directly with oxygen, but does with ozone. Potassium hydrate solution dissolves it, with formation of potassium iodid, and some hypoiodite. Nitric acid oxidizes it to iodic acid. With ammonium hydrate solution it forms the explosive nitrogen iodid.

**Impurities.**—*Non-volatile substances* remain when the I is heated. Water separates as a distinct layer when I is dissolved in carbon disulphid. *Cyanogen iodid* appears in white, acicular crystals among the crystals of sublimed I, when half an ounce of the substance is heated over the water-bath for twenty minutes, in a porcelain capsule, covered with a flat-bottomed flask filled with cold water. The last named is the most serious impurity as it is actively poisonous.

**Toxicology.**—Taken internally, iodin acts both as a local irritant and as a true poison. It is discharged as an alkaline iodid by the urine and perspiration, and when taken in large quantity it appears in the fæces.

The poison should be removed as rapidly as possible by the use of the stomach-pump and of emetics. Farinaceous substances may also be given.

**Hydrogen Iodid—Hydriodic acid—HI—Molecular weight=** 128—*Sp. gr.* 4.443 A.

**Preparation.**—By the decomposition of phosphorus triiodid by water:  $PI_3 + 3H_2O = H_3PO_3 + 3HI$ . Or, in solution by passing hydrogen sulphid through water holding iodine in suspension:  $H_2S + I_2 = 2HI + S$ .

**Properties.**—A colorless gas, forming white fumes on contact with air, and of strongly acid reaction. Under the influence of cold and pressure it forms a yellow liquid, which solidifies at  $-55$  ( $-67$  F.). Water dissolves it to the extent of 425 volumes for each volume of the solvent at  $10^\circ$  ( $50^\circ$  F.).

It is partly decomposed into its elements by heat. Mixed with O it is decomposed, even in the dark, with formation of  $H_2O$  and liberation of I. Under the influence of sunlight the gas is slowly decomposed, although its solutions are not so affected, if they be free from air. Chlorine and bromine decompose it, with liberation of iodine. With many metals it forms iodids. It yields up its H readily and is used in organic chemistry as a source of that element in the nascent state.

**Iodids**—are formed under the same conditions as the chlorids and bromids, which they resemble in their properties. The metallic iodids are soluble in water except  $AgI$ ,  $Hg_2I_2$ , which are insoluble, and  $PbI_2$ , which is very slightly soluble. The iodids of the earth metals are decomposed into oxid and HI on evapora-

tion of their aqueous solutions. Chlorin decomposes the iodids as it does the bromids.

**Analytical Characters.**—(1.) With  $\text{AgNO}_3$ , a yellow ppt., insoluble in  $\text{HNO}_3$ , and in  $\text{NH}_4\text{HO}$ . (2.) With fuming  $\text{HNO}_3$  or with chlorin water, a yellow liquid, which colors starch-paste black or purple, and chloroform violet. (3.) With palladic nitrate, a black ppt., insoluble in cold  $\text{HNO}_3$  and in solutions of alkaline chlorids, but forming a dark brown solution with alkaline iodids.

**Chlorids of Iodin.**—Chlorin and iodine combine with each other in two proportions: **Iodin monochlorid**, or **protochlorid**— $\text{ICl}$  is a red-brown, oily, pungent liquid, formed by the action of dry  $\text{Cl}$  upon  $\text{I}$ , and distilling at  $100^\circ$  ( $212^\circ \text{F.}$ ). **Iodin trichlorid** or **perchlorid**— $\text{ICl}_3$  is a yellow, crystalline solid, having an astringent, acid taste, and a penetrating odor; very volatile; its vapor irritating; easily soluble in water. It is formed by saturating  $\text{H}_2\text{O}$  holding  $\text{I}$  in suspension with  $\text{Cl}$ , and adding concentrated sulphuric acid.  $\text{ICl}_3$  has been used as an antiseptic.

**Oxacids of Iodin.**—The best known of these are the highest two of the series—**iodic** and **periodic acids**.

**Iodic Acid**— $\text{HIO}_3$ —176—is formed as an iodate, whenever  $\text{I}$  is dissolved in a solution of an alkaline hydrate:  $\text{I}_2 + 6\text{KHO} = \text{KIO}_3 + 5\text{KI} + 3\text{H}_2\text{O}$ . As the free acid, by the action of strong oxidizing agents, such as nitric acid, or chloric acid, upon  $\text{I}$ ; or by passing  $\text{Cl}$  for some time through  $\text{H}_2\text{O}$  holding  $\text{I}$  in suspension.

Iodic acid appears in white crystals, decomposable at  $170^\circ$  ( $338^\circ \text{F.}$ ), and quite soluble in  $\text{H}_2\text{O}$ , the solution having an acid reaction, and a bitter, astringent taste.

It is an energetic oxidizing agent, yielding up its  $\text{O}$  readily, with separation of elementary  $\text{I}$  or of  $\text{HI}$ . It is used as a test for the presence of morphin (*q. v.*).

**Periodic Acid**— $\text{HIO}_4$ —192—is formed by the action of  $\text{Cl}$  upon an alkaline solution of sodium iodate. The sodium salt thus obtained is dissolved in nitric acid, treated with silver nitrate, and the resulting silver periodate decomposed with  $\text{H}_2\text{O}$ . From the solution the acid is obtained in colorless crystals, fusible at  $130^\circ$  ( $266^\circ \text{F.}$ ), very soluble in water, and readily decomposable by heat.

## II. SULPHUR GROUP.

### SULPHUR—SELENIUM—TELLURIUM.

The elements of this group are bivalent. With hydrogen they form compounds composed of one volume of the element, in the form of vapor, with two volumes of hydrogen—the combination being attended with a condensation in volume of one-third.

Their hydrates are dibasic acids. They are all solid at ordinary temperatures. The relation of their compounds to each other is shown in the following table :

$\text{H}_2\text{S}$	$\text{SO}_2$	$\text{SO}_3$	$\text{H}_2\text{SO}_2$	$\text{H}_2\text{SO}_3$	$\text{H}_2\text{SO}_4$
$\text{H}_2\text{Se}$	$\text{SeO}_2$	$\text{SeO}_3$	————	$\text{H}_2\text{SeO}_3$	$\text{H}_2\text{SeO}_4$
$\text{H}_2\text{Te}$	$\text{TeO}_2$	$\text{TeO}_3$	————	$\text{H}_2\text{TeO}_3$	$\text{H}_2\text{TeO}_4$
Hydro-ic acid.	Dioxid.	Trioxid.	Hypo-ous acid.	-ous acid.	-ic acid.

### SULPHUR.

*Symbol = S—Atomic weight = 32—Molecular weight = 64—Sp. gr. of vapor = 2.22 A—Fuses at 114 (237.2 F.)—Boils at 447.3 (837 F.).*

**Occurrence.**—Free in crystalline powder, large crystals, or amorphous, in volcanic regions. In combination in sulphids and sulphates, and in albuminoid substances.

**Preparation.**—By purification of the native sulphur, or decomposition of *pyrites*, natural sulphids of iron.

*Crude sulphur* is the product of a first distillation. A second distillation, in more perfectly constructed apparatus, yields *refined sulphur*. During the first part of the distillation, while the air of the condensing chamber is still cool, the vapor of S is suddenly condensed into a fine, crystalline powder, which is **flowers of sulphur**, **sulphur sublimatum** (*U. S.*). Later, when the temperature of the condensing chamber is above 114, the liquid S collects at the bottom, whence it is drawn off and cast into sticks of **roll sulphur**.

**Properties.**—*Physical.*—Sulphur is usually yellow in color. At low temperatures, and in minute subdivision, as in the precipitated milk of sulphur, **sulphur præcipitatum** (*U. S.*), it is almost or quite colorless. Its taste and odor are faint but characteristic. At 114 (237.2 F.) it fuses to a thin yellow liquid, which at 150–160 (302–320 F.) becomes thick and brown; at 330–340 (626–642.2 F.) it again becomes thin and light in color; finally it boils, giving off brownish-yellow vapor at a temperature variously stated between 440 (824 F.) and 448 (838.4 F.). If heated to about 400 (752 F.) and suddenly cooled, it is converted into **plastic sulphur**, which may be moulded into any desired form. It is insoluble in water, sparingly soluble in anilin, phenol, benzol, benzin, and chloroform; readily soluble in protochlorid of sulphur and carbon disulphid. It dissolves in hot alcohol, and crystallizes from the solution, on cooling, in white prismatic crystals. It is dimorphous. When fused sulphur crystallizes it does so in oblique rhombic prisms. Its solution in carbon disulphid deposits it on evaporation in rhombic octahedra. The prismatic

variety is of sp. gr. 1.95 and fuses at 120 (248° F.); the sp. gr. of the octahedral is 2.05, and its fusing point 114.5 (238° F.). The prismatic crystals, by exposure to air, become opaque, by reason of a gradual conversion into octahedra.

*Chemical.*—Sulphur unites readily with other elements, especially at high temperatures. Heated in air or O, it burns with a blue flame to sulphur dioxide,  $\text{SO}_2$ . In H it burns with formation of hydrogen sulphid,  $\text{H}_2\text{S}$ . The compounds of S are similar in constitution, and to some extent in chemical properties, to those of O. In many organic substances S may replace O, as in sulphocyanic acid,  $\text{CNSH}$ , corresponding to cyanic acid,  $\text{CNOH}$ .

Sulphur is used principally in the manufacture of gunpowder; also to some extent in making sulphuric acid, sulphur dioxide, and matches, and for the prevention of fungoid and parasitic growths.

**Hydrogen Monosulphid—Sulphydric acid—Hydrosulphuric acid—Sulphuretted hydrogen— $\text{H}_2\text{S}$** —Molecular weight = 34—Sp. gr.=1.19 A.

*Occurrence.*—In volcanic gases; as a product of the decomposition of organic substances containing S; in solution, in the waters of some mineral springs; and, occasionally, in small quantity, in the gases of the intestine.

*Preparation.*—(1.) By direct union of the elements; either by burning S in H, or by passing H through molten S.

(2.) By the action of nascent H upon sulphuric acid, if the mixture become heated. (See Marsh test for arsenic.)

(3.) By the action of  $\text{HCl}$  upon antimony trisulphid:  $\text{Sb}_2\text{S}_3 + 6\text{HCl} = 2\text{SbCl}_3 + 3\text{H}_2\text{S}$ .

(4.) By the action of dilute sulphuric acid upon ferrous sulphid:  $\text{FeS} + \text{H}_2\text{SO}_4 = \text{FeSO}_4 + \text{H}_2\text{S}$ . This is the method generally used. The gas should be purified by passage over dry calcium chlorid, then through a tube, 20 cent. long, loosely filled with solid iodine and,

finally, through a solution of potassium sulphid.

(5.) By the action of  $\text{HCl}$  upon calcium sulphid:  $\text{CaS} + 2\text{HCl} = \text{CaCl}_2 + \text{H}_2\text{S}$ .

FIG. 24.

The gas is usually obtained in the laboratory by reaction (4), either in an apparatus such as that shown in Fig. 20 (p. 43) or in one of the forms of apparatus shown in Figs. 24, 25. The sulphid is put into the bulb *b*, Fig. 24, through the opening *e*, or into the bottle *b*, Fig. 25. The dilute acid, with which the uppermost and lowest bulbs, Fig. 24, are filled, comes in contact with the sulphid

FIG. 25.

when the stopcock is opened, or in the apparatus, Fig. 25, is poured through the funnel tube *c*. *a* is a wash-bottle partly filled with water.

As ferrous sulphid is liable to contain arsenic, and as hydrogen sulphid generated from it may be contaminated with hydrogen arsenid, the gas, when required for toxicological analysis should always be obtained by reaction (5) in the apparatus, Fig. 24, or should be purified as above directed.

**Properties.**—*Physical.*—A colorless gas, having the odor of rotten eggs and a disgusting taste; soluble in  $H_2O$  to the extent of 3.23 parts to 1 at  $15^\circ$  ( $59^\circ F.$ ); soluble in alcohol. Under 17 atmospheres pressure, or at  $-74^\circ$  ( $-101.2^\circ F.$ ) at the ordinary pressure, it liquefies; at  $-85.5^\circ$  ( $-122^\circ F.$ ) it forms white crystals.

*Chemical.*—Burns in air with formation of sulphur dioxide and water:  $2H_2S + 3O_2 = 2SO_2 + 2H_2O$ . If the supply of oxygen be deficient,  $H_2O$  is formed, and sulphur liberated:  $2H_2S + O_2 = 2H_2O + S_2$ . Mixtures of  $H_2S$  and air or  $O$  explode on contact with flame. Solutions of the gas when exposed to air become oxidized with deposition of  $S$ . Such solutions should be made with boiled  $H_2O$ , and kept in bottles which are completely filled, and well corked. Oxidizing agents,  $Cl$ ,  $Br$ , and  $I$  remove its  $H$

with deposition of S. Hydrogen sulphid and sulphur dioxide mutually decompose each other into water, pentathionic acid and sulphur:  $4\text{SO}_2 + 3\text{H}_2\text{S} = 2\text{H}_2\text{O} + \text{H}_2\text{S}_5\text{O}_6 + \text{S}_2$ .

When the gas is passed through a solution of an alkaline hydrate its S displaces the O of the hydrate to form a sulphhydrate:  $\text{H}_2\text{S} + \text{KHO} = \text{H}_2\text{O} + \text{KHS}$ . With solutions of metallic salts  $\text{H}_2\text{S}$  usually relinquishes its S to the metal:  $\text{CuSO}_4 + \text{H}_2\text{S} = \text{CuS} + \text{H}_2\text{SO}_4$ , a property which renders it of great value in analytical chemistry.

**Physiological.**—Hydrogen sulphid is produced in the intestine by the decomposition of albuminous substances or of taurochloric acid; it also occurs sometimes in abscesses, and in the urine in tuberculosis, variola, and cancer of the bladder. It may also reach the bladder by diffusion from the rectum.

**Toxicology.**—An animal dies almost immediately in an atmosphere of pure  $\text{H}_2\text{S}$ , and the diluted gas is still rapidly fatal. An atmosphere containing one per cent. may be fatal to man,

FIG. 26.

although individuals habituated to its presence can exist in an atmosphere containing three per cent. Even when highly diluted it produces a condition of low fever, and care is to be taken that the air of laboratories in which it is used shall not become contaminated with it. Its toxic powers are due primarily, if not entirely, to its power of reducing and combining with the blood-coloring matter.

The form in which hydrogen sulphid generally produces deleterious effects is as a constituent of the gases emanating from sewers, privies, burial vaults, etc. These give rise to either slow poisoning, as when sewer gases are admitted to sleeping and other apartments by defective plumbing, or to sudden poisoning, as when a person enters a vault or other locality containing the noxious atmosphere.

The treatment should consist in promoting the inhalation of pure air, artificial respiration, cold affusions, and the administration of stimulants.

After death the blood is found to be dark in color, and gives the spectrum shown in Fig. 26, due to sulphæmoglobin.

**Sulphids and Hydrosulphids.**—These compounds bear the

same relation to sulphur that the oxids and hydrates do to oxygen. The two sulphids of arsenic,  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{S}_5$ , correspond to the two oxids,  $\text{As}_2\text{O}_3$  and  $\text{As}_2\text{O}_5$ , and the hydrosulphid of potassium,  $\text{KHS}$ , corresponds to the hydrate,  $\text{KHO}$ .

Many metallic sulphids occur in nature and are important ores of the metals, as the sulphids of zinc, mercury, cobalt, nickel, and iron. They are formed artificially, either by direct union of the elements at elevated temperatures, as in the case of iron:  $\text{Fe} + \text{S} = \text{FeS}$ ; or by reduction of the corresponding sulphate, as in the case of calcium:  $\text{CaSO}_4 + 2\text{C} = \text{CaS} + 2\text{CO}_2$ .

The sulphids are insoluble in  $\text{H}_2\text{O}$ , except those of the alkali metals. Many of the sulphids are soluble in alkaline liquids, and behave as **sulphanhydrids**, forming sulpho- or thio-salts, corresponding to the oxysalts. Thus potassium arsenate,  $\text{K}_3\text{AsO}_4$ , and thioarsenate,  $\text{K}_3\text{AsS}_4$ ; antimonate,  $\text{K}_3\text{SbO}_4$ , and thioantimonate,  $\text{K}_3\text{SbS}_4$ .

The metallic sulphids are decomposed when heated in air, usually with the formation of sulphur dioxide and the metallic oxid; sometimes with the formation of the sulphate; and sometimes with the liberation of the metal, and the formation of sulphur dioxide. The strong mineral acids decompose the sulphids with formation of hydrogen monosulphid.

**Analytical Characters.**—*Hydrogen Sulphid*.—(1.) Blackens paper moistened with lead acetate solution. (2.) Has an odor of rotten eggs.

*Sulphids*.—(1.) Heated in the oxidizing flame of the blowpipe, give a blue flame and odor of  $\text{SO}_2$ . (2.) With a mineral acid give off  $\text{H}_2\text{S}$  (except sulphids of  $\text{Hg}$ ,  $\text{Au}$ , and  $\text{Pt}$ ).

**Sulphur Dioxid**—*Sulphurous oxid, or anhydrid*—**Acidum sulphurosum** (**U. S.**; **Br.**)— $\text{SO}_2$ .—*Molecular weight* = 64—*Sp. gr. of gas* = 2.213; *of liquid* = 1.45—*Boils at*— $10^\circ$  ( $14^\circ \text{F.}$ ); *solidifies at*  $-75^\circ$  ( $-103^\circ \text{F.}$ ).

**Occurrence.**—In volcanic gases and in solution in some mineral waters.

**Preparation.**—(1.) By burning  $\text{S}$  in air or  $\text{O}$ .

(2.) By roasting iron pyrites in a current of air.

(3.) During the combustion of coal or coal-gas containing  $\text{S}$  or its compounds.

(4.) By heating sulphuric acid with copper:  $2\text{H}_2\text{SO}_4 + \text{Cu} = \text{CuSO}_4 + 2\text{H}_2\text{O} + \text{SO}_2$ .

(5.) By heating sulphuric acid with charcoal:  $2\text{H}_2\text{SO}_4 + \text{C} = 2\text{SO}_2 + \text{CO}_2 + 2\text{H}_2\text{O}$ .

(6.) By decomposing calcium sulphite, made into cubes with plaster of Paris, by  $\text{HCl}$ , at the ordinary temperature.

When the gas is to be used as a disinfectant it is usually

obtained by reaction (1) ; in sulphuric acid factories (2) is used ; (3) indicates the method in which atmospheric  $\text{SO}_2$  is chiefly produced ; in the laboratory (4) and (6) are used ; (5) is the process directed by the U. S. and Br. Pharmacopœias.

**Properties.**—*Physical.*—A colorless, suffocating gas, having a disagreeable and persistent taste. Very soluble in  $\text{H}_2\text{O}$ , which at 15 (59 F.) dissolves about 40 times its volume (see below) ; also soluble in alcohol. At  $-10$  (14 F.) it forms a colorless, mobile, transparent liquid, by whose rapid evaporation a cold of  $-65^\circ$  ( $-85^\circ$  F.) is obtained.

*Chemical.*—Sulphur dioxide is neither combustible nor a supporter of combustion. Heated with  $\text{H}$  it is decomposed :  $\text{SO}_2 + 2\text{H}_2 = \text{S} + 2\text{H}_2\text{O}$ . With nascent hydrogen,  $\text{H}_2\text{S}$  is formed :  $\text{SO}_2 + 3\text{H}_2 = \text{H}_2\text{S} + 2\text{H}_2\text{O}$ .

Water not only dissolves the gas, but combines with it to form the true sulphurous acid,  $\text{H}_2\text{SO}_3$ . With solutions of metallic hydrates it forms metallic sulphites :  $\text{SO}_2 + \text{KHO} = \text{KHSO}_3$ ; or  $\text{SO}_2 + 2\text{KHO} = \text{K}_2\text{SO}_3 + \text{H}_2\text{O}$ . A hydrate having the composition  $\text{H}_2\text{SO}_3 \cdot 8\text{H}_2\text{O}$  has been obtained as a crystalline solid, fusible at  $+4^\circ$  ( $39.2^\circ$  F.).

Sulphur dioxide and sulphurous acid solution are powerful reducing agents, being themselves oxidized to sulphuric acid :  $\text{SO}_2 + \text{H}_2\text{O} + \text{O} = \text{H}_2\text{SO}_4$ ; or  $\text{H}_2\text{SO}_3 + \text{O} = \text{H}_2\text{SO}_4$ . It reduces nitric acid with formation of sulphuric acid and nitrogen tetroxid :  $\text{SO}_2 + 2\text{HNO}_3 = \text{H}_2\text{SO}_4 + 2\text{NO}_2$ . It decolorizes organic pigments, without, however, destroying the pigment, whose color may be restored by an alkali or a stronger acid. It destroys  $\text{H}_2\text{S}$ , acting in this instance, not as a reducing, but as an oxidizing agent :  $4\text{SO}_2 + 3\text{H}_2\text{S} = 2\text{H}_2\text{O} + \text{H}_2\text{S}_2\text{O}_6 + \text{S}_2$ . With  $\text{Cl}$  it combines directly under the influence of sunlight to form **sulphuril chlorid** ( $\text{SO}_2$ )'  $\text{Cl}_2$ .

**Analytical Characters.**—(1.) Odor of burning sulphur.

(2.) Paper moistened with starch-paste and iodic acid solution turns blue in air containing 1 in 3,000 of  $\text{SO}_2$ .

**Sulphur Trioxid**—*Sulphuric acid or anhydrid*— $\text{SO}_3$ .—*Molecular weight* = 80—*Sp. gr.* 1.95.

**Preparation.**—(1.) By union of  $\text{SO}_2$  and  $\text{O}$  at 250–300 ( $482$ – $572^\circ$  F.) or in presence of spongy platinum.

(2.) By heating sulphuric acid in presence of phosphoric anhydrid :  $\text{H}_2\text{SO}_4 + \text{P}_2\text{O}_5 = \text{SO}_3 + 2\text{HPO}_3$ .

(3.) By heating dry sodium pyrosulphate :  $\text{Na}_2\text{S}_2\text{O}_7 = \text{Na}_2\text{SO}_4 + \text{SO}_3$ .

(4.) By heating pyrosulphuric acid below 100 ( $212^\circ$  F.), in a retort fitted with a receiver, cooled by ice and salt :  $\text{H}_2\text{S}_2\text{O}_7 = \text{H}_2\text{SO}_4 + \text{SO}_3$ .

**Properties.**—White, silky, odorless crystals which give off white fumes in damp air. It unites with  $H_2O$  with a hissing sound, and elevation of temperature, to form sulphuric acid. When dry it does not redden litmus.

Sulphur trioxid exists in two isomeric (see isomerism) modifications, being one of the few instances of isomerism among mineral substances. The  $\alpha$  modification, liquid at summer temperature, solidifies in colorless prisms at  $16^\circ$  ( $60.8^\circ F.$ ) and boils at  $46^\circ$  ( $114.8^\circ F.$ ). The  $\beta$  isomere is a white, crystalline solid which gradually fuses and passes into the  $\alpha$  form at about  $50^\circ$  ( $122^\circ F.$ ).

### Oxacids of Sulphur.

$H_2SO_2$ Hyposulphurous acid.	$H_2S_2O_7$ Pyrosulphuric acid.
$H_2SO_3$ Sulphurous acid.	$H_2S_2O_6$ Dithionic acid.
$H_2SO_4$ Sulphuric acid.	$H_2S_3O_6$ Trithionic acid.
	$H_2S_4O_6$ Tetrathionic acid.
$H_2S_2O_5$ Thiosulphuric acid.	$H_2S_5O_6$ Pentathionic acid.

**Hyposulphurous Acid**— $H_2SO_2$ —66.—*Hydrosulphurous acid*—Is an unstable body only known in solution, obtained by the action of zinc upon solution of sulphurous acid. It is a powerful bleaching and deoxidizing agent.

**Sulphurous Acid**— $H_2SO_3$ —82.—Although sulphurous acid has not been isolated, it, in all probability, exists in the acid solution, formed when sulphur dioxid is dissolved in water:  $SO_2 + H_2O = SO_3H_2$ . Its salts, the sulphites, are well defined. From the existence of certain organic derivatives (see sulphonie acids) it would seem that two isomeric modifications of the acid may exist. They are distinguished as the *symmetrical*, in which the S atom is quadrivalent,

and the *unsymmetrical*, in which the S atom is hexavalent,

**Sulphites.**—The sulphites are decomposed by the stronger acids, with evolution of sulphur dioxid. Nitric acid oxidizes them to sulphates. The sulphites of the alkali metals are soluble, and are active reducing agents.

The analytical characters of the sulphites are: (1.) With  $HCl$  they give off  $SO_2$ . (2.) With zinc and  $HCl$  they give off  $H_2S$ . (3.) With  $AgNO_3$  they form a white ppt., soluble in excess of sulphite, and depositing metallic Ag when the mixture is boiled. (4.) With  $Ba(NO_3)_2$  they form a white ppt., soluble in  $HCl$ . If chlorine water

be added to the solution so formed a white ppt., insoluble in acids, is produced.

**Sulphuric Acid—Oil of Vitriol—Acidum sulphuricum (U. S.; Br.)**  
—**H<sub>2</sub>SO<sub>4</sub>**—98.

**Preparation.**—(1.) By the union of sulphur trioxid and water :  
 $\text{SO}_3 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4$ .

(2.) By the oxidation of  $\text{SO}_2$  or of S in the presence of water :  
 $2\text{SO}_2 + 2\text{H}_2\text{O} + \text{O}_2 = 2\text{H}_2\text{SO}_4$  ; or  $\text{S}_2 + 2\text{H}_2\text{O} + 3\text{O}_2 = 2\text{H}_2\text{SO}_4$ .

The manufacture of  $\text{H}_2\text{SO}_4$  may be said to be the basis of all chemical industry, as there are but few processes in chemical technology into some part of which it does not enter. The method followed at present, the result of gradual improvement, may be divided into two stages : 1st, the formation of a dilute acid ; 2d, the concentration of this product.

The first part is carried on in immense chambers of timber, lined with lead, and furnishes an acid having a sp. gr. of 1.55, and containing 65 per cent. of true sulphuric acid,  $\text{H}_2\text{SO}_4$ . Into these chambers  $\text{SO}_2$ , obtained by burning sulphur, or by roasting pyrites, is driven, along with a large excess of air. In the chambers it comes in contact with nitric acid, at the expense of which it is oxidized to  $\text{H}_2\text{SO}_4$ , while nitrogen tetroxid (red fumes) is formed :  $\text{SO}_2 + 2\text{HNO}_3 = \text{H}_2\text{SO}_4 + 2\text{NO}_2$ . Were this the only reaction, the disposal of the red fumes would present a serious difficulty and the amount of nitric acid consumed would be very great. A second reaction occurs between the red fumes and  $\text{H}_2\text{O}$ , which is injected in the form of steam, by which nitric acid and nitrogen dioxid are produced :  $3\text{NO}_2 + \text{H}_2\text{O} = 2\text{HNO}_3 + \text{NO}$ . The nitrogen dioxid in turn combines with O to produce the tetroxid, which then regenerates a further quantity of nitric acid, and so on. This series of reactions is made to go on continuously, the nitric acid being constantly regenerated, and acting merely as a carrier of O from the air to the  $\text{SO}_2$ , in such manner that the sum of the reactions may be represented by the equation :  $2\text{SO}_2 + 2\text{H}_2\text{O} + \text{O}_2 = 2\text{H}_2\text{SO}_4$ .

The acid is allowed to collect in the chambers until it has the sp. gr. 1.55, when it is drawn off. This *chamber acid*, although used in a few industrial processes, is not yet strong enough for most purposes. It is concentrated, first by evaporation in shallow leaden pans, until its sp. gr. reaches 1.746. At this point it begins to act upon the lead, and is transferred to platinum stills, where the concentration is completed.

**Varieties.**—Sulphuric acid is met with in several conditions of concentration and purity :

(1.) The *commercial oil of vitriol*, largely used in manufacturing processes, is a more or less deeply colored, oily liquid, vary-

ing in sp. gr. from 1.833 to 1.842, and in concentration from 93 per cent. to 99½ per cent. of true  $\text{H}_2\text{SO}_4$ .

(2.) *C. P. acid* = **Acidum sulphuricum**, *U. S.*; *Br.*, of sp. gr. 1.84, colorless and comparatively pure (see below).

(3.) *Glacial sulphuric acid* is a hydrate of the composition  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ , sometimes called *bihydrated sulphuric acid*, which crystallizes in rhombic prisms, fusible at  $-8.5$  ( $47.3$  F.) when an acid of sp. gr. 1.788 is cooled to that temperature.

(4.) *Ac. sulph. dil.* (*U. S.*; *Br.*) is a dilute acid of sp. gr. 1.069 and containing between 9 and 10 per cent.  $\text{H}_2\text{SO}_4$  (*U. S.*), or of sp. gr. 1.094, containing between 12 and 13 per cent.  $\text{H}_2\text{SO}_4$  (*Br.*).

**Properties.**—*Physical.*—A colorless, heavy, oily liquid; sp. gr. 1.842 at  $12$  ( $53.6$  F.); crystallizes at  $10.5$  ( $50.9$  F.); boils at  $338$  ( $640.4$  F.). It is odorless, intensely acid in taste and reaction, and highly corrosive. It is non-volatile at ordinary temperatures. Mixtures of the acid with  $\text{H}_2\text{O}$  have a lower boiling-point, and lower sp. gr. as the proportion of  $\text{H}_2\text{O}$  increases.

*Chemical.*—At a red heat vapor of  $\text{H}_2\text{SO}_4$  is partly dissociated into  $\text{SO}_3$  and  $\text{H}_2\text{O}$ ; or, in the presence of platinum, into  $\text{SO}_2$ ,  $\text{H}_2\text{O}$  and  $\text{O}$ . When heated with  $\text{S}$ ,  $\text{C}$ ,  $\text{P}$ ,  $\text{Hg}$ ,  $\text{Cu}$ , or  $\text{Ag}$ , it is reduced, with formation of  $\text{SO}_2$ .

Sulphuric acid has a great tendency to absorb  $\text{H}_2\text{O}$ , the union being attended with elevation of temperature, increase of bulk, and diminution of sp. gr. of the acid, and contraction of volume of the mixture. Three parts, by weight, of acid of sp. gr. 1.842, when mixed with one part of  $\text{H}_2\text{O}$  produce an elevation of temperature to  $130$  ( $266$  F.), and the resulting mixture occupies a volume 1.6 less than the sum of the volumes of the constituents. Strong  $\text{H}_2\text{SO}_4$  is a good desiccator of air or gases. It should not be left exposed in uncovered vessels lest, by increase of volume, it overflow. When it is to be diluted with  $\text{H}_2\text{O}$ , the acid should be added to the  $\text{H}_2\text{O}$  in a vessel of thin glass, to avoid the projection of particles or the rupture of the vessel. It is by virtue of its affinity for  $\text{H}_2\text{O}$  that  $\text{H}_2\text{SO}_4$  chars or dehydrates organic substances. Sulphuric acid is a powerful dibasic acid.

**Impurities.**—The commercial acid is so impure that it is only fit for manufacturing and the coarsest chemical uses. The so-called *C. P. acid* may further contain: *Lead*; becomes cloudy when mixed with ten times its volume of  $\text{H}_2\text{O}$ , if the quantity of  $\text{Pb}$  be sufficient. The dilute acid gives a black color with  $\text{H}_2\text{S}$ . *Salts*; leave a fixed residue when the acid is evaporated. *Sulphur dioxide*; gives off  $\text{H}_2\text{S}$  when the acid, diluted with an equal volume of  $\text{H}_2\text{O}$ , comes in contact with  $\text{Zn}$ . *Carbon*; communicates a brown color to the acid. *Arsenic*; is very frequently present. When the acid is to be used for toxicological analysis, the test by  $\text{H}_2\text{S}$  is not sufficient. The acid, diluted with an equal

volume of  $\text{H}_2\text{O}$ , is to be introduced into a Marsh apparatus, in which no visible stain should be produced during an hour. *Oxids of nitrogen*; are almost invariably present; they communicate a pink or red color to pure brucin.

**Sulphates.**—Sulphuric acid being dibasic, there exist two sulphates of the univalent metals:  $\text{H}\text{KSO}_4$  and  $\text{K}_2\text{SO}_4$ , and but one sulphate of each bivalent metal:  $\text{CaSO}_4$ . The sulphates of Ba, Ca, Sr, and Pb are insoluble, or very sparingly soluble, in  $\text{H}_2\text{O}$ . Other sulphates are soluble in  $\text{H}_2\text{O}$ , but all are insoluble in alcohol.

**Analytical Characters.**—(1.) Barium chlorid (or nitrate): a white ppt., insoluble in acids. The ppt., dried and heated with charcoal, forms  $\text{BaS}$ , which, with  $\text{HCl}$ , gives off  $\text{H}_2\text{S}$ . (2.) Plumbic acetate forms a white ppt., insoluble in dilute acids. (3.) Calcium chlorid forms a white ppt., either immediately or on dilution with two volumes of alcohol: insoluble in dilute  $\text{HCl}$  or  $\text{HNO}_3$ .

**Toxicology.**—Sulphuric acid is an active corrosive, and may be, if taken in sufficient quantity in a highly diluted state, a true poison. The concentrated acid causes death, either within a few hours, by corrosion and perforation of the walls of the stomach and œsophagus, or, after many weeks, by starvation, due to destruction of the gastric mucous membrane and closure of the pyloric orifice of the stomach.

The treatment is the same as that for corrosion by  $\text{HCl}$ . (See p. 85.)

**Thiosulphuric Acid**—*Hyposulphurous acid*— $\text{H}_2\text{S}_2\text{O}_3$ —114—may be considered as sulphuric acid,  $\text{H}_2\text{SO}_4$ , in which one atom of oxygen has been replaced by one of sulphur. The acid itself has not been isolated, being decomposed, on liberation from the thio-sulphates, into sulphur, water and sulphur dioxid:  $\text{H}_2\text{S}_2\text{O}_3 = \text{S} + \text{SO}_2 + \text{H}_2\text{O}$ .

**Pyrosulphuric Acid.**—*Fuming sulphuric acid*—*Nordhausen oil of vitriol*—*Disulphuric hydrate*— $\text{H}_2\text{S}_2\text{O}_7$ —*Molecular weight* = 178—*Sp. gr.* = 1.9—*Boils at*  $52^\circ.2$  ( $126^\circ \text{ F.}$ ).

**Preparation.**—By distilling dry ferrous sulphate; and purification of the product by repeated crystallizations and fusions, until a substance fusing at  $35^\circ$  ( $95^\circ \text{ F.}$ ) is obtained.

**Properties.**—The commercial Nordhausen acid, which is a mixture of  $\text{H}_2\text{S}_2\text{O}_7$  with excess of  $\text{SO}_3$ , or of  $\text{H}_2\text{SO}_4$ , is a brown, oily liquid, which boils below  $100$  ( $212^\circ \text{ F.}$ ) giving off  $\text{SO}_3$ ; and is solid or liquid according to the temperature. It is used chiefly as a solvent for indigo, and in the anilin industry.

## SELENIUM AND TELLURIUM.

Se—79.5. Te—128.

These are rare elements which form compounds similar to those of sulphur. Elementary selenium is used in some forms of electrical apparatus.

## III. NITROGEN GROUP.

## NITROGEN—PHOSPHORUS—ARSENIC—ANTIMONY.

The elements of this group are trivalent or quinquivalent, occasionally univalent. With hydrogen they form non-acid compounds, composed of one volume of the element in the gaseous state with three volumes of hydrogen, the union being attended with a condensation of volume of one-half. Their hydrates are acids containing one, two, three, or four atoms of replaceable hydrogen.

Bismuth, frequently classed in this group, is excluded, owing to the existence of the nitrate  $\text{Bi}(\text{NO}_3)_3$ . The relations existing between the compounds of the elements of this group are shown in the following table:

$\text{NH}_3$ ,	$\text{N}_2\text{O}$ ,	$\text{NO}$ ,	$\text{N}_2\text{O}_3$ ,	$\text{NO}_2$ ,	$\text{N}_2\text{O}_5$ ,	—
$\text{PH}_3$ ,	—	—	$\text{P}_2\text{O}_3$ ,	—	$\text{P}_2\text{O}_5$ ,	$\text{H}_3\text{PO}_3$ ,
$\text{AsH}_3$ ,	—	—	$\text{As}_2\text{O}_3$ ,	—	$\text{As}_2\text{O}_5$ ,	—

## NITROGEN.

*Azote*—Symbol=**N**—Atomic weight=14—Molecular weight=28—*Sp. gr.*=0.9701—One litre weighs 1.254 grams—Name from *νίτρον*=nitre, *γένεσις*=source; or from *ἀ*, privative *ζωή*=life—Discovered by Mayow in 1669.

**Occurrence.**—Free in atmospheric air and in volcanic gases. In combination in the nitrates, in ammoniacal compounds and in a great number of animal and vegetable substances.

**Preparation.**—(1.) By removal of O from atmospheric air; by

burning P in air, or by passing air slowly over red-hot copper. It is contaminated with  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , etc.

(2.) By passing Cl through excess of ammonium hydrate solution. If ammonia be not maintained in excess, the Cl reacts with the ammonium chlorid formed, to produce the explosive nitrogen chlorid.

(3.) By heating ammonium nitrite,  $(\text{NH}_4) \text{NO}_2$ ; or a mixture of ammonium chlorid and potassium nitrite.

**Properties.**—A colorless, odorless, tasteless, non-combustible gas; not a supporter of combustion; very sparingly soluble in water.

It is very slow to enter into combination, and most of its compounds are very prone to decomposition, which may occur explosively or slowly. Nitrogen combines directly with O under the influence of electric discharges; and with H under like conditions, and, indirectly, during the decomposition of nitrogenized organic substances. It combines directly with magnesium, boron, vanadium and titanium.

Nitrogen is not poisonous, but is incapable of supporting respiration.

**Atmospheric Air.**—The alchemists considered air as an element, until Mayow, in 1669, demonstrated its complex nature. It was not, however, until 1770 that Priestley repeated the work of Mayow; and that the compound nature of air, and the characters of its constituents were made generally known by the labors (1770–1781) of Priestley, Rutherford, Lavoisier, and Cavendish. The older chemists used the terms *gas* and *air* as synonymous.

**Composition.**—Air is not a chemical compound, but a mechanical mixture of O and N, with smaller quantities of other gases. Leaving out of consideration about 0.4 to 0.5 per cent. of other gases, air consists of 20.93 O and 79.07 N, by volume; or 23 O and 77 N, by weight; proportions which vary but very slightly at different times and places; the extremes of the proportion of O found having been 20.908 and 20.999.

That air is not a compound is shown by the fact that the proportion of its constituents does not represent a relation between their atomic weights, or between any multiples thereof; as well as by the solubility of air in water. Were it a compound it would have a definite degree of solubility of its own, and the dissolved gas would have the same composition as when free. But each of its constituents dissolves in  $\text{H}_2\text{O}$  according to its own solubility, and air dissolved in  $\text{H}_2\text{O}$  at  $14^\circ.1$  ( $57.4^\circ \text{F.}$ ) consists of N and O, not in the proportion given above, but in the proportion 66.76 to 33.24.

Besides these two main constituents, air contains about 4–5

thousandths of its bulk of other substances: vapor of water, carbon dioxid, ammoniacal compounds, hydrocarbons, ozone, oxids of nitrogen, and solid particles held in suspension.

**Vapor of Water.**—Atmospheric moisture is either visible, as in fogs and clouds, when it is in the form of a finely divided liquid; or invisible, as vapor of water. The amount of  $H_2O$  which a given volume of air can hold, without precipitation, varies according to the temperature and the pressure. It happens rarely that air is as highly charged with moisture as it is capable of being for the existing temperature. The difference between the amount of water which the air is capable of holding at the existing temperature, and that which it actually does hold is its **fraction of saturation**, or **hygrometric state**, or **relative humidity**. Ordinarily air contains from 66 to 70 per cent. of its possible amount of moisture. If the quantity be less than this, the air is too dry, and causes a parched sensation, and the sense of "stiffness" so common in furnace-heated houses. If it be greater, evaporation from the skin is impeded, and the air is oppressive if warm.

The actual amount of moisture in air is determined by passing a known volume through tubes filled with calcium chlorid: whose increase in weight represents the amount of  $H_2O$  in the volume of air used. The fraction of saturation is determined by instruments called **hygrometers**, **hygroscopes** or **psychrometers**.

**Carbon dioxid.**—The quantity of carbon dioxid in free air varies from 3 to 6 parts in 10,000 by volume. (See Carbon dioxid.)

**Ammoniacal compounds.**—Carbonate, nitrate, and nitrite of ammonium occur in small quantity (0.1 to 6.0 parts per million of  $NH_3$ ) in air, as products of the decomposition of nitrogenized organic substances. They are absorbed and assimilated by plants.

**Nitric and nitrous acids**, usually in combination with ammonium, are produced either by the oxidation of combustible substances containing N, or by direct union of N and  $H_2O$  during discharges of atmospheric electricity. Rain-water, falling during thunder-showers, has been found to contain as much as 3.71 per million of  $HNO_3$ . (See Hydrogen peroxid, p. 77.)

**Sulphuric and sulphurous acids** occur, in combination with  $NH_4$ , in the air over cities, and manufacturing districts, where they are produced by the oxidation of S, existing in coal and coal-gas.

**Hydrocarbons** have been detected in the air of cities, and of swampy places, in small quantities...

**Solid particles** of the most diverse nature are always present in air and become visible in a beam of sunlight. Sodium chlorid is almost always present, always in the neighborhood of salt water. Air contains myriads of germs of vegetable organisms, mould,

etc., which are propagated by the transportation of these germs by air-currents. It seems probable, also, that the germs or poisons by which certain diseases are propagated float in the air.

FIG. 27.

The continued inhalation of air containing large quantities of solid particles in suspension may cause severe pulmonary disorder, by mere mechanical irritation, and apart from any poisonous quality in the substance; such is the case with the air of carpeted ball-rooms, and of the workshops of certain trades, furniture-polishers, metal-filers, etc.

Atmospheric dust is best collected by an instrument such as is shown in Fig. 27. A disk of thin glass is fastened upon the plate *b*, over the small opening in *A*, and its lower surface moistened with a mixture of equal parts of water and glycerin, the opening *C* is connected with an aspirator. After one or more cubic metres of air have been drawn through the apparatus, the thin glass is detached and the deposit examined microscopically. The deposit may be also examined for bacteria by the proper methods.

**Ammonia.** *Hydrogen nitrid—Volatile alkali—* $\text{NH}_3$ *—Molecular weight*=17—*Sp. gr.*=0.589 *A—Liquefies at*  $-40^\circ$  ( $-40^\circ \text{ F.}$ )—*Boils at*  $-33.7$  ( $-28.7^\circ \text{ F.}$ )—*Solidifies at*  $-75^\circ$  ( $-103^\circ \text{ F.}$ )—*A litre weighs* 0.7655 gram.

**Preparation.**—(1.) By union of nascent H with N.

(2.) By decomposition of organic matter containing N, either spontaneously or by destructive distillation.

(3.) By heating a mixture of dry slacked lime with ammonium chlorid:  $2\text{NH}_4\text{Cl} + \text{CaH}_2\text{O}_2 = \text{CaCl}_2 + 2\text{H}_2\text{O} + 2\text{NH}_3$ .

(4.) By heating solution of ammonium hydrate:  $\text{NH}_4\text{HO} \rightarrow \text{NH}_3 + \text{H}_2\text{O}$ .

**Properties.**—*Physical.*—A colorless gas, having a pungent odor, and an acrid taste. It is very soluble in  $\text{H}_2\text{O}$ , 1 volume of which

at 0° (32° F.) dissolves 1050 vols.  $\text{NH}_3$ , and at 15° (59° F.), 727 vols.  $\text{NH}_3$ . Alcohol and ether also dissolve it readily. Liquid ammonia is a colorless, mobile fluid, used in ice machines for producing artificial cold, the liquid absorbing a great amount of heat in volatilizing.

*Chemical.*—At a red heat ammonia is decomposed into a mixture of N and H, occupying double the volume of the original gas. It is similarly decomposed by the prolonged passage through it of discharges of electricity. It is not readily combustible, yet it burns in an atmosphere of O with a yellowish flame. Mixtures of  $\text{NH}_3$  with O, nitrogen monoxid, or nitrogen dioxid, explode on contact with flame.

The solution of ammonia in  $\text{H}_2\text{O}$  constitutes a strongly alkaline liquid, known as **aqua ammoniæ**, which is possessed of strongly basic properties. It is neutralized by acids with the formation of crystalline salts, which are also formed, without liberation of hydrogen, by direct union of gaseous  $\text{NH}_3$ , with acid vapors. The ammoniacal salts and the alkaline base in aqua ammoniæ are compounds of a radical, **ammonium**,  $\text{NH}_4$ , which forms compounds corresponding to those of potassium or sodium. The compound formed by the union of ammonia and water is **ammonium hydrate** or **hydroxid**,  $\text{NH}_4\text{HO}$ :  $\text{NH}_3 + \text{H}_2\text{O} = \text{NH}_4\text{HO}$ ; and that formed by the union of hydrochloric acid and ammonia is **ammonium chlorid**,  $\text{NH}_4\text{Cl}$ :  $\text{NH}_3 + \text{HCl} = \text{NH}_4\text{Cl}$ .

**Hydroxylamin— $\text{NH}_2\text{HO}$ —33.**—The amins and amids (q.v.) are compounds derived from ammonia by the substitution of radicals for a part or all of its hydrogen. This substance, which is intermediate in composition between ammonia and ammonium hydrate, may be considered as ammonia, one of whose hydrogen atoms has been replaced by the radical hydroxyl, HO. It is obtained in aqueous solution by the union of nascent hydrogen with nitrogen dioxid:  $\text{NO} + \text{H}_2 = \text{NH}_2\text{HO}$ ; or by the action of nascent hydrogen upon nitric acid:  $\text{HNO}_3 + 3\text{H}_2 = 2\text{H}_2\text{O} + \text{NH}_2\text{HO}$ . Hydroxylamin is only known in solution and in combination. Its aqueous solution, which probably contains the corresponding hydrate,  $\text{NH}_2\text{O}, \text{HO}$ , is strongly alkaline and behaves with regard to acids as does ammonium hydrate solution, forming salts corresponding to those of ammonium. Thus hydroxylammonium chlorid,  $\text{NH}_2\text{OCl}$ , crystallizes in prisms or tables, fusible at 100° (212° F.), and decomposed into HCl,  $\text{H}_2\text{O}$  and  $\text{NH}_4\text{Cl}$  at a slightly higher temperature.

Hydroxylammonium chlorid has been used in the treatment of cutaneous disorders. It is an actively toxic agent, converting oxyhæmoglobin into methæmoglobin.

**Nitrogen Monoxid.** *Nitrous oxid—Laughing gas—Nitrogen protoxid—* $\text{N}_2\text{O}$ *—Molecular weight=44—Sp. gr.=1.527—Fuses at*  $-100$  ( $-148^\circ \text{F.}$ )*—Boils at*  $-87$  ( $-124^\circ \text{F.}$ )*—Discovered in 1776 by Priestley.*

**Preparation.**—By heating ammonium nitrate:  $(\text{NH}_4)\text{NO}_3 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$ . To obtain a pure product there should be no ammonium chlorid present (as an impurity of the nitrate), and the heat should be applied gradually, and not allowed to exceed  $250$  ( $482^\circ \text{F.}$ ), and the gas formed should be passed through wash-bottles containing sodium hydrate and ferrous sulphate.

**Properties.**—*Physical.*—A colorless, odorless gas, having a sweetish taste; soluble in  $\text{H}_2\text{O}$ ; more so in alcohol. Under a pressure of 30 atmospheres, at  $0$  ( $32^\circ \text{F.}$ ), it forms a colorless, mobile liquid which, when dissolved in carbon disulphid and evaporated *in vacuo*, produces a cold of  $-140$  ( $-220^\circ \text{F.}$ ).

*Chemical.*—It is decomposed by a red heat and by the continuous passage of electric sparks. It is not combustible, but is, after oxygen, the best supporter of combustion known.

**Physiological.**—Although, owing to the readiness with which  $\text{N}_2\text{O}$  is decomposed into its constituent elements, and the nature and relative proportions of these elements, it is capable of maintaining respiration longer than any gas except oxygen or air: an animal will live for a short time only in an atmosphere of pure nitrous oxid. When inhaled, diluted with air, it produces the effects first observed by Davy in 1799: first an exhilaration of spirits, frequently accompanied by laughter, and a tendency to muscular activity, the patient sometimes becoming aggressive; afterward there is complete anæsthesia, and loss of consciousness. It has been much used, by dentists especially, as an anæsthetic in operations of short duration, and in one or two instances anæsthesia has been maintained by its use for nearly an hour.

A solution in water under pressure, containing five volumes of the gas, is sometimes used for internal administration.

**Nitrogen Dioxid.** *Nitric oxid—* $\text{NO}$ *—Molecular weight=30—Sp. gr.=1.039—Discovered by Hales in 1772.*

**Preparation.**—By the action of copper on moderately diluted nitric acid in the cold:  $3\text{Cu} + 8\text{HNO}_3 = 3\text{Cu}(\text{NO}_3)_2 + 4\text{H}_2\text{O} + 2\text{NO}$ ; the gas being collected after displacement of air from the apparatus.

**Properties.**—A colorless gas, whose odor and taste are unknown; very sparingly soluble in  $\text{H}_2\text{O}$ ; more soluble in alcohol.

It combines with O, when mixed with that gas or with air, to form the reddish-brown nitrogen tetroxid. It is absorbed by solution of ferrous sulphate, to which it communicates a dark

brown or black color. It is neither combustible nor a good supporter of combustion, although ignited C and P continue to burn in it, and the alkaline metals, when heated in it, combine with its O with incandescence.

**Nitrogen Trioxid.** *Nitrous anhydrid*— $\text{N}_2\text{O}_3$ —76—Is prepared by the direct union of nitrogen dioxid and oxygen at low temperatures, or by decomposing liquefied nitrogen tetroxid with a small quantity of  $\text{H}_2\text{O}$  at a low temperature:  $4\text{NO}_2 + \text{H}_2\text{O} = 2\text{HNO}_3 + \text{N}_2\text{O}_3$ . It is a dark indigo-blue liquid, which, boiling at about  $0^\circ$  ( $32^\circ \text{F.}$ ), is partly decomposed. It solidifies at  $-82^\circ$  ( $-115.6^\circ \text{F.}$ ).

**Nitrogen Tetroxid.** *Nitrogen peroxid—Hyponitric acid—Nitrous fumes*— $\text{NO}_2$ —*Molecular weight*=46—*Sp. gr.*=1.584 (at  $154^\circ \text{C.}$ )—*Boils at*  $22^\circ$  ( $71.6^\circ \text{F.}$ )—*Solidifies at*  $9^\circ$  ( $15.8^\circ \text{F.}$ ).

**Preparation.**—(1.) By mixing one volume O with two volumes  $\text{NO}$ ; both dry and ice-cold.

(2.) By heating perfectly dry lead nitrate, O being also produced:  $2\text{Pb}(\text{NO}_3)_2 = 2\text{PbO} + 4\text{NO}_2 + \text{O}_2$ .

(3.) By dropping strong nitric acid upon a red-hot platinum surface.

**Properties.**—When pure and dry, it is an orange-yellow liquid at the ordinary temperature; the color being darker the higher the temperature. The red fumes, which are produced when nitric acid is decomposed by starch or by a metal, consist of  $\text{NO}_2$ , mixed with  $\text{N}_2\text{O}_3$ . It dissolves in nitric acid, forming a dark yellow liquid, which is blue or green if  $\text{N}_2\text{O}_3$  be also present. With  $\text{SO}_2$  it combines to form a solid, crystalline compound, which is sometimes produced in the manufacture of  $\text{H}_2\text{SO}_4$ . This substance, which forms the **lead chamber crystals**, is a substituted sulphurous acid, **nitrosulphonic acid**,  $\text{NO}_2\text{SO}_2\text{OH}$  (see sulphonic acids). A small quantity of  $\text{H}_2\text{O}$  decomposes  $\text{NO}_2$  into  $\text{HNO}_3$  and  $\text{N}_2\text{O}_3$ , which latter colors it green or blue. A larger quantity of  $\text{H}_2\text{O}$  decomposes it into  $\text{HNO}_3$  and  $\text{NO}$ . By bases it is transformed into a mixture of nitrite and nitrate:  $2\text{NO}_2 + 2\text{KHO} = \text{KNO}_2 + \text{KNO}_3 + \text{H}_2\text{O}$ .

It is an energetic oxydant, for which it is largely used. With certain organic substances it does not behave as an oxydant, but becomes substituted as an univalent radical; thus with benzol it forms nitro-benzol:  $\text{C}_6\text{H}_5(\text{NO}_2)$ .

**Toxicology.**—The brown fumes given off during many processes, in which nitric acid is decomposed, are dangerous to life. All such operations, when carried on on a small scale, as in the laboratory, should be conducted under a hood or some other arrangement, by which the fumes are carried into the open air. When,

in industrial processes, the volume of gas formed becomes such as to be a nuisance when discharged into the air, it should be utilized in the manufacture of  $\text{H}_2\text{SO}_4$  or absorbed by  $\text{H}_2\text{O}$  or an alkaline solution.

An atmosphere contaminated with brown fumes is more dangerous than one containing  $\text{Cl}$ , as the presence of the latter is more immediately annoying. At first there is only coughing, and it is only two to four hours later that a difficulty in breathing is felt, death occurring in ten to fifteen hours. At the autopsy the lungs are found to be extensively disorganized and filled with black fluid.

Even air containing small quantities of brown fumes, if breathed for a long time, produces chronic disease of the respiratory organs. To prevent such accidents, thorough ventilation in locations where brown fumes are liable to be formed is imperative. In cases of spilling nitric acid, safety is to be sought in retreat from the apartment until the fumes have been replaced by pure air from without.

**Nitrogen Pentoxid.** *Nitric anhydrid*— $\text{N}_2\text{O}_5$ —*Molecular weight*=108—*Fuses at* 30 (86° F.)—*Boils at* 47° (116°.6 F.).

**Preparation.**—(1.) By decomposing dry silver nitrate with dry  $\text{Cl}$  in an apparatus entirely of glass:  $4\text{AgNO}_3 + 2\text{Cl}_2 = 4\text{AgCl} + 2\text{N}_2\text{O}_5 + \text{O}_2$ .

(2.) By removing water from fuming nitric acid with phosphorus pentoxid:  $6\text{HNO}_3 + \text{P}_2\text{O}_5 = 2\text{H}_3\text{PO}_4 + 3\text{N}_2\text{O}_5$ .

**Properties.**—Prismatic crystals at temperatures above 30 (86° F.). It is very unstable, being decomposed by a heat of 50 (122° F.); on contact with  $\text{H}_2\text{O}$ , with which it forms nitric acid; and even spontaneously. Most substances which combine readily with  $\text{O}$ , remove that element from  $\text{N}_2\text{O}_5$ .

**Nitrogen Acids.**—Three are known, either free or in combination, corresponding to the three oxids containing uneven numbers of  $\text{O}$  atoms:

**Hyponitrous acid**— $\text{H}_2\text{N}_2\text{O}_2$ —31—Known only in combination. Silver hyponitrite is formed by reduction of sodium nitrate by nascent  $\text{H}$  and decomposition with silver nitrate.

**Nitrous acid**— $\text{HNO}_2$ —47—has not been isolated, although its salts, the nitrites, are well-defined compounds:  $\text{M}'\text{NO}_2$  or  $\text{M}'(\text{NO}_2)_2$ .

The *nitrites* occur in nature, in small quantity, in natural waters, where they result from the decomposition of nitrogenous

organic substances; also in saliva. They are produced by heating the corresponding nitrate, either alone or in the presence of a readily oxidizable metal, such as lead. Solutions of the nitrites are readily decomposed by the mineral acids, with evolution of brown fumes. They take up oxygen readily and are hence used as reducing agents. Solutions of potassium permanganate are instantly decolorized by nitrites. A mixture of thin starch paste and zinc iodid solution is colored blue by nitrites, which decompose the iodid, liberating the iodine. A solution of metaphenylenediamine, in the presence of free acid, is colored brown by very minute traces of a nitrite, the color being due to the formation of triamido-azobenzol (Bismark brown).

**Nitric Acid.** *Aqua fortis*—*Hydrogen nitrate*—*Acidum nitricum*—**U.S.**; **Br.**— $\text{HNO}_3$ —63.

**Preparation.**—(1.) By the direct union of its constituent elements under the influence of electric discharges.

(2.) By the decomposition of an alkaline nitrate by strong  $\text{H}_2\text{SO}_4$ . With moderate heat a portion of the acid is liberated:  $2\text{NaNO}_3 + \text{H}_2\text{SO}_4 = \text{NaHSO}_4 + \text{NaNO}_3 + \text{HNO}_3$ , and at a higher temperature the remainder is given off:  $\text{NaNO}_3 + \text{NaHSO}_4 = \text{Na}_2\text{SO}_4 + \text{HNO}_3$ . This is the reaction used in the manufacture of  $\text{HNO}_3$ .

**Varieties.**—**Commercial**—a yellowish liquid, impure, and of two degrees of concentration: **single aqua fortis**; sp. gr. about 1.25 = 39%  $\text{HNO}_3$ ; and **double aqua fortis**; sp. gr. about 1.4 = 64%  $\text{HNO}_3$ . **Fuming**—a reddish-yellow liquid, more or less free from impurities; charged with oxids of nitrogen. Sp. gr. about 1.5. Used as an oxidizing agent. **C. P.**—a colorless liquid, sp. gr. 1.522, which should respond favorably to the tests given below. **Acidum nitricum, U. S.**; **Br.**—a colorless acid, of sp. gr. 1.42 = 70%  $\text{HNO}_3$ . **Acidum nitricum dilutum, U. S.**; **Br.**—the last mentioned, diluted with  $\text{H}_2\text{O}$  to sp. gr. 1.059 = 10%  $\text{HNO}_3$  (*U. S.*), or to sp. gr. 1.101 = 17.44%  $\text{HNO}_3$  (*Br.*).

**Properties.**—**Physical.**—The pure acid is a colorless liquid; sp. gr. 1.522; boils at  $86^\circ$  ( $186.8^\circ \text{F.}$ ); solidifies at  $-40^\circ$  ( $-40^\circ \text{F.}$ ); gives off white fumes in damp air; and has a strong acid taste and reaction. The sp. gr. and boiling-point of dilute acids vary with the concentration. If a strong acid be distilled, the boiling-point gradually rises from  $86^\circ$  ( $186.8^\circ \text{F.}$ ) until it reaches  $123^\circ$  ( $253.4^\circ \text{F.}$ ), when it remains constant, the sp. gr. of distilled and distillate being 1.42 = 70%  $\text{HNO}_3$ . If a weak acid be taken originally the boiling-point rises until it becomes stationary at the same point.

**Chemical.**—When exposed to air and light, or when strongly heated,  $\text{HNO}_3$  is decomposed into  $\text{NO}_2$ ,  $\text{H}_2\text{O}$  and  $\text{O}$ . Nitric acid is a valuable oxydant; it converts I, P, S, C, B, and Si or their

lower oxids into their highest oxids; it oxidizes and destroys most organic substances, although with some it forms products of substitution. Most of the metals dissolve in  $\text{HNO}_3$  as nitrates, a portion of the acid being at the same time decomposed into  $\text{NO}$  and  $\text{H}_2\text{O}$ :  $4\text{HNO}_3 + 3\text{Ag} = 3\text{AgNO}_3 + \text{NO} + 2\text{H}_2\text{O}$ . The chemical activity of  $\text{HNO}_3$  is much reduced, or even almost arrested, when the intervention of nitrous acid is prevented by the presence of carbanid. The so-called "noble metals," gold and platinum, are not dissolved by either  $\text{HNO}_3$  or  $\text{HCl}$ , but dissolve as chlorids in a mixture of the two acids, called *aqua regia*. In this mixture the two acids mutually decompose each other according to the equations:  $\text{HNO}_3 + 3\text{HCl} = 2\text{H}_2\text{O} + \text{NOCl} + \text{Cl}_2$  and  $2\text{HNO}_3 + 6\text{HCl} = 4\text{H}_2\text{O} + 2\text{NOCl}_2 + \text{Cl}_2$  with formation of nitrosyl chlorid,  $\text{NOCl}$  and bichlorid,  $\text{NOCl}_2$ , and nascent  $\text{Cl}$ ; the last named combining with the metal. Iron dissolves easily in dilute  $\text{HNO}_3$ , but if dipped into the concentrated acid, it is rendered *passive*, and does not dissolve when subsequently brought in contact with the dilute acid. This passive condition is destroyed by a temperature of  $40^\circ$  ( $104^\circ \text{F.}$ ) or by contact with  $\text{Pt}$ ,  $\text{Ag}$  or  $\text{Cu}$ . When  $\text{HNO}_3$  is decomposed by zinc or iron, or in the porous cup of a Grove battery,  $\text{N}_2\text{O}_3$  and  $\text{NO}_2$  are formed, and dissolve in the acid, which is colored dark yellow, blue or green. An acid so charged is known as *nitroso-nitric acid*. Nitric acid is monobasic.

**Impurities.**—*Oxids of Nitrogen* render the acid yellow, and decolorize potassium permanganate when added to the dilute acid. *Sulphuric acid* produces cloudiness when  $\text{BaCl}_2$  is added to the acid, diluted with two volumes of  $\text{H}_2\text{O}$ . *Chlorin, iodin* cause a white ppt. with  $\text{AgNO}_3$ . *Iron* gives a red color when the diluted acid is treated with ammonium sulphocyanate. *Salts*, leave a fixed residue when the acid is evaporated to dryness on platinum.

**Nitrates.**—The nitrates of  $\text{K}$  and  $\text{Na}$  occur in nature. Nitrates are formed by the action of  $\text{HNO}_3$  on the metals, or on their oxids or carbonates. They have the composition  $\text{MNO}_3$ ,  $\text{M}''(\text{NO}_3)_2$  or  $\text{M}'''(\text{NO}_3)_3$ , except certain basic salts, such as the sesquibasic lead nitrate,  $\text{Pb}(\text{NO}_3)_2 \cdot 2\text{PbO}$ . With the exception of a few basic salts, the nitrates are all soluble in water. When heated, they fuse and act as powerful oxidants. They are decomposed by  $\text{H}_2\text{SO}_4$  with liberation of  $\text{HNO}_3$ .

**Analytical Characters.**—(1.) Add an equal volume of concentrated  $\text{H}_2\text{SO}_4$ , cool, and float on the surface of the mixture a solution of  $\text{FeSO}_4$ . The lower layer becomes gradually colored brown, black or purple, beginning at the top.

(2.) Boil in a test-tube a small quantity of  $\text{HCl}$ , containing enough sulphindigotic acid to communicate a blue color, add the suspected solution and boil again; the color is discharged.

(3.) If acid, neutralize with  $\text{KHO}$ , evaporate to dryness, add to

the residue a few drops of  $\text{H}_2\text{SO}_4$  and a crystal of brucin (or some sulphanilic acid); a red color is produced.

(4.) Add  $\text{H}_2\text{SO}_4$  and Cu to the suspected liquid and boil, brown fumes appear (best visible by looking into the mouth of the test-tube).

(5.) A solution of diphenylamin in concentrated  $\text{H}_2\text{SO}_4$  (.01 gram. in 100 c.c.) is colored blue by nitric acid. A similar color is produced by other reducing agents.

(6.) To 0.5 c.c. nitrate solution add 1 drop aqueous solution of resorcin (10%), and 1 drop HCl (15%), and float on the surface of 2 c.c. concentrated  $\text{H}_2\text{SO}_4$ ; a purple-red band.

**Toxicology.**—Although most of the nitrates are poisonous when taken internally in sufficiently large doses, their action seems to be due rather to the metal than to the acid radical. Nitric acid itself is one of the most powerful of corrosives.

Any animal tissue with which the concentrated acid comes in contact is immediately disintegrated. A yellow stain, afterward turning to dirty brownish, or, if the action be prolonged, an eschar, is formed. When taken internally, its action is the same as upon the skin, but, owing to the more immediately important function of the parts, is followed by more serious results (unless a large cutaneous surface be destroyed).

The symptoms following its ingestion are the same as those produced by the other mineral acids, except that all parts with which the acid has come in contact, including vomited shreds of mucous membrane, are colored yellow. The treatment is the same as that indicated when  $\text{H}_2\text{SO}_4$  or HCl have been taken; *i.e.* neutralization of the corrosive by magnesia or soap.

**Compounds of Nitrogen with the Halogens.**—**Nitrogen chlorid**— $\text{NCl}_3$ —120.5—is formed by the action of excess of Cl upon  $\text{NH}_3$  or an ammoniacal compound. It is an oily, light yellow liquid; sp. gr. 1.653; has been distilled at  $71^\circ$  ( $159^\circ.8 \text{ F.}$ ). When heated to  $96^\circ$  ( $204^\circ.8 \text{ F.}$ ), when subjected to concussion, or when brought in contact with phosphorus, alkalies or greasy matters it is decomposed, with a violent explosion, into one volume N and three volumes Cl.

**Nitrogen bromid**— $\text{NBr}_3$ —254—has been obtained, as a reddish-brown, syrupy liquid, very volatile, and resembling the chlorid in its properties, by the action of potassium bromid upon nitrogen chlorid.

**Nitrogen iodid**— $\text{NI}_3$ —395—When iodine is brought in contact with ammonium hydrate solution, a dark brown or black powder, highly explosive when dried, is formed. This substance varies in composition according to the conditions under which the action occurs; sometimes the iodid alone is formed; under other circumstances it is mixed with compounds containing N, I and H.

## PHOSPHORUS.

*Symbol*=P—*Atomic weight*=31—*Molecular weight*=124—*Sp. gr. of vapor*=4.2904 A—*Name from* φῶς=light, φέρω=I bear—*Discovered by* Brandt in 1669—**Phosphorus (U. S.; Br.).**

**Occurrence.**—Only in combination; in the mineral and vegetable worlds as phosphates of Ca, Mg, Al, Pb, K, Na. In the animal kingdom as phosphates of Ca, Mg, K and Na, and in organic combination.

**Preparation.**—From bone-ash, in which it occurs as tricalcic phosphate. Three parts of bone-ash are digested with 2 parts of strong  $\text{H}_2\text{SO}_4$ , diluted with 20 volumes  $\text{H}_2\text{O}$ , when insoluble calcic sulphate and the soluble monocalcic phosphate, or "superphosphate," are formed:  $\text{Ca}_3(\text{PO}_4)_2 + 2\text{H}_2\text{SO}_4 = \text{H}_4\text{Ca}(\text{PO}_4)_2 + 2\text{CaSO}_4$ . The solution of superphosphate is filtered off and evaporated, the residue is mixed with about one-fourth its weight of powdered charcoal and sand, and the mixture heated, first to redness, finally to a white heat, in earthenware retorts, whose beaks dip under water in suitable receivers. During the first part of the heating the monocalcic phosphate is converted into metaphosphate:  $\text{CaH}_4(\text{PO}_4)_2 = \text{Ca}(\text{PO}_3)_2 + 2\text{H}_2\text{O}$ ; which is in turn reduced by the charcoal, with formation of carbon monoxid and liberation of phosphorus, while the calcium is combined as silicate:  $2\text{Ca}(\text{PO}_3)_2 + 2\text{SiO}_2 + 5\text{C}_2 = 2\text{CaSiO}_3 + 10\text{CO} + \text{P}_4$ .

Another process consists in dissolving bone-ash or mineral phosphate in  $\text{HNO}_3$ .  $\text{K}_2\text{SO}_4$  is then added to the solution, and the greater part of the Ca removed by filtration as  $\text{CaSO}_4$ . Mercurous phosphate is then formed by addition of mercurous nitrate to the solution. The dried Hg salt is finally mixed with carbon, and decomposed by heat, when Hg and P distil over.

The crude product is purified by fusion, first under a solution of bleaching powder, next under ammoniacal  $\text{H}_2\text{O}$ , and finally under water containing a small quantity of  $\text{H}_2\text{SO}_4$  and potassium dichromate. It is then strained through leather and cast into sticks under warm  $\text{H}_2\text{O}$ .

**Properties.**—*Physical.*—Phosphorus is capable of existing in four allotropic forms:

(1.) *Ordinary, or yellow variety*, in which it usually occurs in commerce. This is a yellowish, translucent solid of the consistency of wax. Below 0° (32° F.) it is brittle; it fuses at 44°.3 (111°.7 F.); and boils at 290° (554° F.) in an atmosphere not capable of acting upon it chemically. Its vapor is colorless; sp. gr.=4.5A—65 H at 1040° (1940° F.). It volatilizes below its boiling-point, and  $\text{H}_2\text{O}$  boiled upon it gives off steam charged with its vapor. Exposed to

air, it gives off white fumes, and produces ozone. It is luminous in the dark. It is insoluble in  $H_2O$ ; sparingly soluble in alcohol and ether; soluble in carbon disulphid, and in the fixed and volatile oils. It crystallizes on evaporation of its solutions in octahedra or dodecahedra. Sp. gr. 1.83 at  $10^\circ$  ( $50^\circ$  F.).

(2.) *White phosphorus* is formed as a white, opaque pellicle upon the surface of the ordinary variety, when this is exposed to light under aerated  $H_2O$ . Sp. gr. 1.515 at  $15^\circ$  ( $59^\circ$  F.). When fused it reproduces ordinary phosphorus without loss of weight.

(3.) *Black variety* is formed when ordinary phosphorus is heated to  $70^\circ$  ( $158^\circ$  F.) and suddenly cooled.

(4.) *Red variety* is produced from the ordinary by maintaining it at from  $240$  ( $464^\circ$  F.) to  $280$  ( $536^\circ$  F.) for two or three days, in an atmosphere of carbon dioxid; and, after cooling, washing out the unaltered yellow phosphorus with carbon disulphid. It is also formed upon the surface of the yellow variety, when it is exposed to direct sunlight.

It is a reddish, odorless, tasteless solid, which does not fume in air, nor dissolve in the solvents of the yellow variety. Sp. gr. 2.1. Heated to  $500$  ( $932^\circ$  F.) with lead, in the absence of air, it dissolves in the molten metal, from which it separates on cooling in violet-black, rhombohedral crystals, of sp. gr. 2.34. If prepared at  $250$  ( $482^\circ$  F.) it fuses below that temperature, and at  $260$  ( $500^\circ$  F.) is transformed into the yellow variety, which distils. The crystalline product does not fuse. It is not luminous at ordinary temperatures.

*Chemical.*—The most prominent property of P is the readiness with which it combines with O. The yellow variety ignites and burns with a bright flame if heated in air to  $60$  ( $140^\circ$  F.), or if exposed in a finely divided state to air at the ordinary temperature; with formation of  $P_2O_3$ ;  $P_2O_5$ ;  $H_3PO_3$ , or  $H_3PO_4$ , according as O is present in excess or not, and according as the air is dry or moist. The temperature of ignition of yellow P is so low that it must be preserved under boiled water. By directing a current of O upon it, P may be burned under  $H_2O$ , heated above  $45$  ( $113^\circ$  F.). The red variety combines with O much less readily, and may be kept in contact with air without danger.

The luminous appearance of yellow P is said to be due to the formation of ozone. It does not occur in pure O at the ordinary temperature, nor in air under pressure, nor in the absence of moisture, nor in the presence of minute quantities of carbon disulphid, oil of turpentine, alcohol, ether, naphtha, and many gases.

Yellow phosphorus burns in Cl with formation of  $PCl_3$  or  $PCl_5$ , according as P or Cl is present in excess. Both yellow and red varieties combine directly with Cl, Br, and I.

Phosphorus is not acted on by HCl or cold  $\text{H}_2\text{SO}_4$ . Hot  $\text{H}_2\text{SO}_4$  oxidizes it with formation of phosphorous acid and sulphur dioxide:  $\text{P}_4 + 6\text{H}_2\text{SO}_4 = 4\text{H}_3\text{PO}_3 + 6\text{SO}_2$ . Nitric acid oxidizes it violently to phosphoric acid and nitrogen di- and tetr-oxides:  $12\text{HNO}_3 + \text{P}_4 = 4\text{H}_3\text{PO}_4 + 8\text{NO}_2 + 4\text{NO}$ .

Phosphorus is a reducing agent. When immersed in cupric sulphate solution, it becomes covered with a coating of metallic copper. In silver nitrate solution it produces a black deposit of silver phosphid.

**Toxicology.**—The red variety differs from the other allotropic forms of phosphorus in not being poisonous, probably owing to its insolubility, and in being little liable to cause injury by burning.

The burns produced by yellow phosphorus are more serious than a like destruction of cutaneous surface by other substances. A burning fragment of P adheres tenaciously to the skin, into which it burrows. One of the products of the combustion is metaphosphoric acid (q. v.) which, being absorbed, gives rise to true poisoning. Burns by P should be washed immediately with dilute javelle water, liq. sodæ chlorinatae, or solution of chlorid of lime. Yellow P should never be allowed to come in contact with the skin, except it be under cold water.

Yellow P is one of the most insidious of poisons. It is taken or administered usually as "ratsbane" or match-heads. The former is frequently starch paste, charged with phosphorus; the latter, in the ordinary sulphur match, a mixture of potassium chlorate, very fine sand, phosphorus, and a coloring matter. The symptoms in acute phosphorus-poisoning appear with greater or less rapidity, according to the dose, and the presence or absence in the stomach of substances which favor its absorption. Their appearance may be delayed for days, but as a rule they appear within a few hours. A disagreeable garlicky taste in the mouth, and heat in the stomach are first observed, the latter gradually developing into a burning pain, accompanied by vomiting of dark-colored matter, which, when shaken in the dark, is phosphorescent; low temperature and dilatation of the pupils. In some cases, death follows at this point suddenly, without the appearance of any further marked symptoms. Usually, however, the patient rallies, seems to be doing well, until, suddenly, jaundice makes its appearance, accompanied by retention of urine, and frequently delirium, followed by coma and death.

There is no known chemical antidote to phosphorus. The treatment is, therefore, limited to the removal of the unabsorbed portions of the poison by the action of an emetic, zinc or copper sulphate, or apomorphia, as expeditiously as possible, and the administration of French oil of turpentine—the older the oil the

better—as a physiological antidote. The use of fixed oils or fats is to be avoided, as they favor the absorption of the poison, by their solvent action. The prognosis is very unfavorable.

As commercial phosphorus is usually contaminated with arsenic, the effects of the latter substance may also appear in poisoning by the former.

**Analysis.**—When, after a death supposed to be caused by phosphorus, chemical evidence of the existence of the poison in the body, etc., is desired, the investigation must be made as soon after

FIG. 28.

death as possible, for the reason that the element is rapidly oxidized, and the detection of the higher stages of oxidation of phosphorus is of no value as evidence of the administration of the element, because they are normal constituents of the body and of the food.

The detection of elementary phosphorus in a systematic toxicological analysis is connected with that of prussic acid, alcohol, ether, chloroform, and other volatile poisons. The substances under examination are diluted with  $H_2O$ , acidulated with  $H_2SO_4$ , and heated over a sand-bath in the flask *a* (Fig. 28). This flask is connected with a  $CO_2$  generator, *b*, whose stopcock is closed,

and with a Liebig's condenser, *c*, which is in darkness (the operation is best conducted in a dark room), and so placed as to deliver the distillate into the flask *d*. The odor of the distillate is noted. In the presence of P it is usually alliaceous. The condenser is also observed. If, at the point of greatest condensation, a faint, luminous ring be observed (in the absence of *all* reflections), it is proof positive of the presence of unoxidized phosphorus. The absence, however, of that poison is not to be inferred from the absence of the luminous ring (see above). If this fail to appear, when one-third the fluid contents of the flask *a* have distilled over, the condenser is disconnected at *e*, and in its place the absorbing apparatus, Fig. 29, partly filled with a neu-

Fig. 29.

Fig. 30.

tral solution of silver nitrate, is adjusted by a rubber tube attached at *g*, and a slow and constant stream of  $\text{CO}_2$  is caused to traverse the apparatus from *b*, Fig. 28. If, during continuation of the distillation, no black deposit is formed in the silver solution, the absence of P may be inferred. If a black deposit be formed, it must be further examined to determine if it be silver phosphid. For this purpose the apparatus shown in Fig. 30 is used. In the bottle *a* hydrogen is generated from *pure* Zn and  $\text{H}_2\text{SO}_4$ , the gas passing through the drying-tube *b*, filled with fragments of  $\text{CaCl}_2$ , and out through the platinum tip at *c*; *d* and *e* are pinch-cocks. When the apparatus is filled with  $\text{H}$ , *d* is closed until the funnel-tube *f* is three-quarters filled with the liquid from *a*; then *e* is closed and *d* opened, and the black silver deposit, which has been collected on a filter and washed, is

thrown into *f*; *e* is then slightly opened and the escaping gas ignited at *c*, the size of the flame being regulated by *e*. If the deposit contain P, the flame will have a green color; and, when examined with the spectroscope, will give the spectrum of bright bands shown in Fig. 31.

*Chronic phosphorus poisoning*, or *Lucifer disease*, occurs among operatives engaged in the dipping, drying, and packing of phosphorus matches. Those engaged in the manufacture of phosphorus itself are not so affected. Sickly women and children are most subject to it. The cause of the disease has been ascribed to the presence of arsenic, and to the formation of oxids of phosphorus, and of ozone. The progress of the disorder is slow, and its culminating manifestation is the destruction of one or both maxillæ by necrosis.

The frequency of the disease may be in some degree diminished by thorough ventilation of the shops, by frequent washing of the face and mouth with a weak solution of sodium carbonate, and

FIG. 31.

by exposing oil of turpentine in saucers in the workshops. None of these methods, however, effect a perfect prevention, which can only be attained by the substitution of the red variety of phosphorus for the yellow in this industry.

**Hydrogen Phosphids.**—**Gaseous hydrogen phosphid**—*Phosphonia*, *Phosphamin*, *Phosphin*— $\text{PH}_3$ —34—A colorless gas, having a strong alliaceous odor, which is obtained pure by decomposing phosphonium iodid,  $\text{PH}_4\text{I}$ , with  $\text{H}_2\text{O}$ . Mixed with H and vapor of  $\text{P}_2\text{H}_4$ , it is produced, as a spontaneously inflammable gas, by the action of hot, concentrated solution of potassium hydrate on P, or by decomposition of calcium phosphid by  $\text{H}_2\text{O}$ . It is highly poisonous. After death, the blood is found to be of a dark violet color, and to have, in a great measure, lost its power of absorbing oxygen.

**Liquid hydrogen phosphid**— $\text{P}_2\text{H}_4$ —66—is the substance whose vapor communicates to  $\text{PH}_3$  its property of igniting on contact with air. It is separated by passing the spontaneously inflammable  $\text{PH}_3$  through a bulb tube, surrounded by a freezing mixture.

It is a colorless, heavy liquid, which is decomposed by exposure to sunlight, or to a temperature of 30° (86° F.).

**Solid hydrogen phosphid**— $\text{P}_2\text{H}_4$ —126—is a yellow solid, formed when  $\text{P}_2\text{H}_4$  is decomposed by sunlight. It is not phosphorescent and only ignites at 160° (320° F.).

**Oxids of Phosphorus.**—Two are known:  $\text{P}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$ .

**Phosphorus trioxid**—*Phosphorous anhydrid, Phosphorous oxid*— $\text{P}_2\text{O}_3$ —110—is formed when P is burned in a very limited supply of perfectly dry air, or O. It is a white, flocculent solid, which, on exposure to air, ignites by the heat developed by its union with  $\text{H}_2\text{O}$  to form phosphorous acid.

**Phosphorus pentoxid**—*Phosphoric anhydrid, Phosphoric oxid*— $\text{P}_2\text{O}_5$ —142—is formed when P is burned in an excess of dry O. It is a white, flocculent solid, which has almost as great a tendency to combine with  $\text{H}_2\text{O}$  as has  $\text{P}_2\text{O}_3$ . It absorbs moisture rapidly, deliquescing to a highly acid liquid, containing, not orthophosphoric, but metaphosphoric acid. It is used as a drying agent.

**Phosphorus acids.**—Five oxyacids of phosphorus are known:

Only those H atoms which are connected with the P atoms through O atoms are basic. Hence  $\text{H}_3\text{PO}_2$  is monobasic;  $\text{H}_3\text{PO}_3$  is dibasic;  $\text{H}_3\text{PO}_4$  is tribasic;  $\text{H}_4\text{P}_2\text{O}_7$  is tetrabasic, and  $\text{HPO}_3$  is monobasic.

**Hypophosphorous acid**— $\text{H}_3\text{PO}_2$ —66—is a crystalline solid, or,

more usually, a strongly acid, colorless syrup. It is oxidized by air to a mixture of  $\text{H}_3\text{PO}_3$  and  $\text{H}_3\text{PO}_4$ .

The hypophosphites as well as the free acid, are powerful reducing agents.

Phosphorous acid— $\text{H}_3\text{PO}_3$ —82—is formed by decomposition of phosphorous trichlorid by water:  $\text{PCl}_3 + 3\text{H}_2\text{O} = \text{H}_3\text{PO}_3 + 3\text{HCl}$ . It is a highly acid syrup, is decomposed by heat, and is a strong reducing agent.

Phosphoric acid—*Orthophosphoric acid*—*Common, or tribasic, phosphoric acid*—*Acidum phosphoricum*, U. S.; Br. — $\text{H}_3\text{PO}_4$ —98—does not occur free in nature, but is widely disseminated in combination, in the phosphates, in the three kingdoms of nature.

It is prepared: (1) By converting bone phosphate,  $\text{Ca}_3(\text{PO}_4)_2$ , into the corresponding lead or barium salt,  $\text{Pb}_3(\text{PO}_4)_2$  or  $\text{Ba}_3(\text{PO}_4)_2$ , and decomposing the former by  $\text{H}_2\text{S}$ , or the latter by  $\text{H}_2\text{SO}_4$ . (2) By oxidizing P by dilute  $\text{HNO}_3$ , aided by heat. The operation should be conducted with caution, and heat gradually applied by the sand-bath. It is best to use red phosphorus. This is the process directed by the U. S. and Br. Pharm.

The concentrated acid is a colorless, transparent, syrupy liquid; still containing  $\text{H}_2\text{O}$ , which it gives off on exposure over  $\text{H}_2\text{SO}_4$ , leaving the pure acid, in transparent, deliquescent, prismatic crystals. It is decomposed by heat to form, first, pyrophosphoric acid, then metaphosphoric acid. It is tribasic.

If made from arsenical phosphorus, and commercial phosphorus is usually arsenical, it is contaminated with arsenic acid, whose presence may be recognized by Marsh's test (q. v.). The acid should not respond to the indigo and ferrous sulphate tests for  $\text{HNO}_3$ .

Phosphates.—Phosphoric acid being tribasic the phosphates have the composition  $\text{M}'\text{H}_2\text{PO}_4$ ;  $\text{M}'_2\text{HPO}_4$ ;  $\text{M}'_3\text{PO}_4$ ;  $\text{M}'(\text{H}_2\text{PO}_4)_2$ ;  $\text{M}'_2(\text{HPO}_4)$ ;  $\text{M}'_3(\text{PO}_4)$ ;  $\text{M}'\text{M}''\text{PO}_4$ ; and  $\text{M}''\text{PO}_4$ . The monometallic salts are all soluble and are strongly acid. Of the dimetallic salts, those of the alkali metals only are soluble and their solutions are faintly alkaline; the others are unstable, and exhibit a marked tendency to transformation into monometallic or trimetallic salts. The normal phosphates of the alkali metals are the only soluble trimetallic phosphates. Their solutions are strongly alkaline, and they are decomposed even by weak acids:

All the monometallic phosphates, except those of the alkali metals, are decomposed by ammonium hydrate, with precipitation of the corresponding trimetallic salt.

**Analytical Characters.**—(1) With ammoniacal solution of silver nitrate, a yellow precipitate. (2) With solution of ammonium molybdate in  $\text{HNO}_3$ , a yellow precipitate. (3) With magnesia mixture,\* a white, crystalline precipitate, soluble in acids, insoluble in ammonium hydrate.

**Pyrophosphoric acid**— $\text{H}_4\text{P}_2\text{O}_7$ —178.—When orthophosphoric acid (or hydro-disodic phosphate) is maintained at  $213^\circ$  ( $415.4^\circ \text{F.}$ ), two of its molecules unite, with the loss of the elements of a molecule of water:  $2\text{H}_3\text{PO}_4 = \text{H}_4\text{P}_2\text{O}_7 + \text{H}_2\text{O}$ , to form pyrophosphoric acid.

**Metaphosphoric acid**—*Glacial phosphoric acid*— $\text{HPO}_3$ —80—is formed by heating  $\text{H}_3\text{PO}_4$  or  $\text{H}_4\text{P}_2\text{O}_7$  to near redness:  $\text{H}_3\text{PO}_4 = \text{HPO}_3 + \text{H}_2\text{O}$ ; or  $\text{H}_4\text{P}_2\text{O}_7 = 2\text{HPO}_3 + \text{H}_2\text{O}$ . It is usually obtained from bone phosphate; this is first converted into ammonium phosphate, which is then subjected to a red heat.

It is a white, glassy, transparent solid, odorless, and acid in taste and reaction. Slowly deliquescent in air, it is very soluble in  $\text{H}_2\text{O}$ , although the solution takes place slowly, and is accompanied by a peculiar crackling sound. In constitution and basicity it resembles  $\text{HNO}_3$ .

The metaphosphates are capable of existing in five polymeric modifications (see polymerism): Mono- di- tri- tetra- and hexameta-phosphates:  $\text{MPO}_3$ ;  $\text{M}_2(\text{PO}_3)_2$  and  $\text{M}''(\text{PO}_3)_2$ ;  $\text{M}'_3(\text{PO}_3)_3$ ;  $\text{M}'_4(\text{PO}_3)_4$  and  $\text{M}''_2(\text{PO}_3)_4$ ; and  $\text{M}'_6(\text{PO}_3)_6$ .

**Action of the Phosphates on the Economy.**—The salts of orthophosphoric acid are important constituents of animal tissues, and give rise, when taken internally, in reasonable doses, to no untoward symptoms. The acid itself may act deleteriously, by virtue of its acid reaction. Meta- and pyro-phosphoric acids, even when taken in the form of neutral salts, have a distinct action (the pyro being the more active) upon the motor ganglia of the heart, producing diminution of the blood-pressure, and, in comparatively small doses, death from cessation of the heart's action.

**Compounds of Phosphorus with the Halogens.**—**Phosphorus trichlorid**— $\text{PCl}_3$ —137.5—is obtained by heating P in a limited supply of Cl. It is a colorless liquid; sp. gr. 1.61; has an irritating odor; fumes in air; boils at  $76^\circ$  ( $169^\circ \text{F.}$ ). Water decomposes it with formation of  $\text{H}_3\text{PO}_3$  and  $\text{HCl}$ .

**Phosphorus pentachlorid**— $\text{PCl}_5$ —208.5—is formed when P is burnt in excess of Cl. It is a light yellow, crystalline solid: gives off irritating fumes; and is decomposed by  $\text{H}_2\text{O}$ .

**Phosphorus oxychlorid**— $\text{POCl}_3$ —153.5—is formed by the ac-

\* Made by dissolving 11 pts. crystallized magnesium chlorid and 28 pts. ammonium chlorid in 130 pts. water, adding 70 pts. dilute ammonium hydrate and filtering after two days.

tion of a limited quantity of  $H_2O$  on the pentachlorid:  $PCl_5 + H_2O = POCl_3 + 2HCl$ . It is a colorless liquid; sp. gr. 1.7; boils at  $110^\circ$  ( $230^\circ$  F.); and solidifies at  $-10^\circ$  ( $+14^\circ$  F.).

With bromin P forms compounds similar in composition and properties to the chlorin compounds. With iodin it forms two compounds,  $PI_2$  and  $PI_3$ . With fluorin it forms two compounds,  $PF_3$  and  $PF_5$ , the former liquid, the second gaseous.

### ARSENIC.

*Symbol—As—Atomic weight=75—Molecular weight=300—Sp. gr. of solid=5.75; of vapor=10.64 at 860 (1580 F.).—Name from ἀρσενικόν=orpiment.*

**Occurrence.**—Free in small quantity; in combination as arsenids of Fe, Co, and Ni, but most abundantly in the sulphids, orpiment and realgar, and in arsenical iron pyrites or mispickel.

**Preparation.**—(1.) By heating mispickel in clay cylinders, which communicate with sheet iron condensing tubes.

(2.) By heating a mixture of arsenic trioxid and charcoal; and purifying the product by resublimation.

**Properties.**—*Physical.*—A brittle, crystalline, steel gray solid, having a metallic lustre, or a dull, black, amorphous solid. At the ordinary pressure, and without contact of air, it volatilizes without fusion at  $180^\circ$  ( $356^\circ$  F.); under strong pressure it fuses at a dull red heat. Its vapor is yellowish, and has the odor of garlic. It is insoluble in  $H_2O$  and in other liquids unless chemically altered.

*Chemical.*—Heated in air it is converted into the trioxid and ignites somewhat below a red heat. In O it burns with a brilliant, bluish-white light. In dry air it is not altered, but in the presence of moisture its surface becomes tarnished by oxidation. In  $H_2O$  it is slowly oxidized, a portion of the oxid dissolving in the water. It combines readily with Cl, Br, I, and S, and with most of the metals. With H it only combines when that element is in the nascent state. Warm, concentrated  $H_2SO_4$  is decomposed by As, with formation of  $SO_2$ ,  $As_2O_3$ , and  $H_2O$ . Nitric acid is readily decomposed, giving up its O to the formation of arsenic acid. With hot HCl, arsenic trichlorid is formed. When fused with potassium hydrate, arsenic is oxidized, H is given off, and a mixture of potassium arsenite and arsenid remains, which by greater heat is converted into arsenic, which volatilizes, and potassium arsenate, which remains.

Elementary arsenic enters into the composition of fly poison and of shot, and is used in the manufacture of certain pigments and fire-works.

**Compounds of Arsenic and Hydrogen.**—Two are known: the solid  $\text{As}_2\text{H}$  (?), and the gaseous,  $\text{AsH}_3$ .

**Hydrogen arsenid**—*Arseniuretted or arsenetted hydrogen* = *Arsenia*—*Arsenamin*— $\text{AsH}_3$ —*Molecular weight* = 78—*Sp. gr.* = 2.695 *A*—*Liquefies at*  $-40^\circ$  ( $-40^\circ \text{ F.}$ ).

**Formation.**—(1.) By the action of  $\text{H}_2\text{O}$  upon an alloy, obtained by fusing together native sulphid of antimony, 2 pts.; cream of tartar, 2 pts.; and arsenic trioxid, 1 pt.

(2.) By the action of dilute  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  upon the arsenids of  $\text{Zn}$  and  $\text{Sn}$ .

(3.) Whenever a reducible compound of arsenic is in presence of nascent hydrogen. (See Marsh test.)

(4.) By the action of  $\text{H}_2\text{O}$  upon the arsenids of the alkali metals.

(5.) By the combined action of air, moisture and organic matter upon arsenical pigments.

(6.) By the action of hot solution of potassium hydrate upon reducible compounds of  $\text{As}$  in the presence of zinc.

**Properties.**—*Physical.*—A colorless gas: having a strong alliaceous odor; soluble in 5 vols. of  $\text{H}_2\text{O}$ , free from air.

*Chemical.*—It is neutral in reaction. In contact with air and moisture its  $\text{H}$  is slowly removed by oxidation, and elementary  $\text{As}$  deposited. It is also decomposed into its elements by the passage through it of luminous electric discharges: and when subjected to a red heat. It is acted on by dry  $\text{O}$  at ordinary temperatures with the formation of a black deposit which is at first solid hydrogen arsenid, later elementary  $\text{As}$ . A mixture of  $\text{AsH}_3$  and  $\text{O}$ , containing 3 vols.  $\text{O}$  and 2 vols.  $\text{AsH}_3$ , explodes when heated, forming  $\text{As}_2\text{O}_3$  and  $\text{H}_2\text{O}$ . If the proportion of  $\text{O}$  be less, elementary  $\text{As}$  is deposited.

The gas burns with a greenish flame, from which a white cloud of arsenic trioxid arises. A cold surface, held above the flame, becomes coated with a white, crystalline deposit of the oxid. If the flame be cooled, by the introduction of a cold surface into it, the  $\text{H}$  alone is oxidized, and elementary  $\text{As}$  is deposited. Chlorin decomposes the gas explosively, with formation of  $\text{HCl}$  and arsenic trioxid. Bromin and iodin behave similarly, but with less violence.

All oxidizing agents decompose it readily;  $\text{H}_2\text{O}$  and arsenic trioxid being formed by the less active oxidants, and  $\text{H}_2\text{O}$  and arsenic acid by the more active. Solid potassium hydrate decomposes the gas partially, and becomes coated with a dark deposit, which seems to be elementary arsenic. Solutions of the alkaline hydrates absorb and decompose it:  $\text{H}$  is given off and an alkaline

arsenite remains in the solution. Many metals, when heated in  $H_2As$ , decompose it with formation of a metallic arsenid and liberation of hydrogen. Solution of silver nitrate is reduced by it; elementary silver is deposited, and the solution contains arsenic trioxid.

Although  $H_2S$  and  $H_3As$  decompose each other to a great extent, with formation of arsenic trisulphid, in the presence of air, the two gases do not act upon each other at the ordinary temperature, even in the direct sunlight, either dry or in the presence of  $H_2O$ , when air is absent. Hence in making  $H_2S$  for use in toxicological analysis, materials free from As must be used; or the  $H_2S$  must be purified as described on p. 92.

**Compounds of Arsenic and Oxygen.**—Two are known:  $As_2O_3$  and  $As_2O_5$ .

Probably the gray substance formed by the action of moist air on elementary arsenic is a lower oxid.

**Arsenic trioxid**—*Arsenious anhydrid*—*Arsenious oxid*—*White arsenic*—*Arsenic*—*Arsenious acid*—**Acidum arseniosum**, U. S.; Br.— $As_2O_3$ —198.

**Preparation.**—(1.) By roasting the native sulphids of arsenic in a current of air.

(2.) By burning arsenic in air or oxygen.

**Properties.**—*Physical.*—It occurs in two distinct forms: *crystallized* or "*powdered*," and *vitreous* or *porcelainous*. When freshly fused, it appears in colorless or faintly yellow, transparent, vitreous masses, having no visible crystalline structure. Shortly, however, these masses become opaque upon the surface, and present the appearance of porcelain. This change, which is due to the substance assuming the crystalline form, slowly progresses toward the centre of the mass, which, however, remains vitreous for a long time. The change is attended by the slow liberation of heat, and, if it be made to take place more rapidly, a faint light is visible in obscurity. When arsenic trioxid is sublimed, if the vapors be condensed upon a cool surface, it is deposited in the form of brilliant octahedral crystals, which are larger and more perfect the nearer the temperature of the condensing surface is to  $180$  ( $356$  F.). The crystalline variety may be converted into the vitreous, by keeping it for some time at a temperature near its point of volatilization.

The taste of arsenic trioxid is at first faintly sweet, afterward somewhat acrid, metallic, and nauseating. It is odorless. In aqueous solution (see below) it has a faintly acid reaction. The sp. gr. of the vitreous variety is 3.785; that of the crystalline, 3.689.

Its solubility in water varies with the temperature, the method of making the solution, the presence of foreign substances and the nature of the oxid :

	Transparent Form.	Opaque Form.	Fresh Crystalline Oxid.
1,000 parts of cold distilled water, after standing 24 hours, dissolved.....	1.74 parts.	1.16 parts.	2.0 parts.
1,000 parts of boiling water poured on the oxid, and allowed to stand for 24 hours, dissolved.....	10.12 parts.	5.4 parts.	15.0 parts.
1,000 parts of water boiled for one hour, the quantity being kept uniform by the addition of boiling water from time to time, and filtered immediately, dissolved.....	64.5 parts.	76.5 parts.	87.0 parts.

The vitreous variety is more soluble than the crystalline, but, by prolonged boiling, the crystalline is converted into the vitreous, or, at all events, the solubility of the two forms becomes the same. The solution of the crystallized oxid in cold  $\text{H}_2\text{O}$  is always very slow (the vitreous oxid dissolves more rapidly), and continues for a long time. If white arsenic be thrown upon cold  $\text{H}_2\text{O}$ , only a portion of it sinks, the remainder floating upon the surface, notwithstanding its high specific gravity. This is due to a repulsion of the  $\text{H}_2\text{O}$  from the surfaces of the crystals, which also accounts, to some extent at least, for its slow solution. Even after several days, cold  $\text{H}_2\text{O}$  does not dissolve all the oxid with which it is in contact. If one part of oxid be digested with 80 parts of  $\text{H}_2\text{O}$ , at ordinary temperatures for several days, the resulting solution contains  $\frac{1}{30}$ ; with 160 parts  $\text{H}_2\text{O}$ ,  $\frac{1}{180}$ ; with 240 parts,  $\frac{1}{240}$ ; with 1,000 parts  $\text{H}_2\text{O}$ ,  $\frac{1}{1200}$ ; and even when 16,000 or 100,000 parts of  $\text{H}_2\text{O}$  are used, a portion of the oxid remains undissolved. Arsenious oxid, which had remained in contact with cold  $\text{H}_2\text{O}$  in closed vessels for eighteen years, dissolved to the extent of 1 part in 54 of  $\text{H}_2\text{O}$ , or 18.5 parts in 1,000, which may be given as the maximum solubility of the crystallized oxid in cold water. The power of  $\text{H}_2\text{O}$  of holding the acid in solution, once it is dissolved, is not the same as its power of dissolving it. If a concentrated solution be made, by boiling  $\text{H}_2\text{O}$  upon the oxid, and filtering hot, the filtrate may be evaporated to one-half its original bulk, without depositing any of the acid, of which this concentrated fluid now contains as much as one part in six of

H<sub>2</sub>O, or 166.6 parts per 1,000. If a hot solution of the acid be allowed to cool, the solution will contain 62.5 parts per 1,000 at 16° (60°.8 F.), and 50 parts per 1,000 at 7° (44°.6 F.).

The solubility of the oxid in alcohol varies with the strength of the spirit, and the nature of the oxid, the vitreous variety being more soluble in strong than in weak alcohol, while the contrary is the case with the crystalline, as is shown in the following table:

1,000 parts dissolve		Alcohol at 56%.	Alcohol at 79%.	Alcohol at 86%.	Absolute alcohol.
Crystallized oxid	{At 15° (59° F.). . . . .	16.80	14.30	7.15	0.25
	{At the boiling-point	48.95	45.51	31.97	34.02
Vitreous oxid at 15° (59° F.). . . . .		5.04	5.40	.....	10.60

The presence of the mineral acids and alkalies, ammonia and ammoniacal salts, alkaline carbonates, tartaric acid, and the tartrates, increases the solubility of arsenic trioxid in water. It is less soluble in fluids containing fats, or extractive or other organic matters (the various liquid articles of food), than it is in pure water.

In chemico-legal cases, in which the question of the solubility of arsenic is likely to arise, it must not be forgotten that the quantity of As<sub>2</sub>O<sub>3</sub> which a person may unconsciously take in a given quantity of fluid is not limited, under certain circumstances, to that which the fluid is capable of *dissolving*. A much greater quantity than this may be taken, while in suspension in the liquid, especially if it be mucilaginous.

CHEMICAL.—Its solutions are acid in reaction, and probably contain the true arsenious acid, H<sub>3</sub>AsO<sub>3</sub>. They are neutralized by bases, with formation of arsenites. Solutions of sodium or potassium hydrate dissolve it, with formation of the corresponding arsenite. It is readily reduced, with separation of As, when heated with hydrogen, carbon, or potassium cyanid, and at lower temperatures by more active reducing agents. Oxidizing agents, such as HNO<sub>3</sub>, the hydrates of chlorin, chromic acid, convert it into arsenic pentoxid or arsenic acid. Its solution, acidulated with HCl and boiled in presence of copper, deposits on the metal a gray film, composed of an alloy of Cu and As.

**Arsenic pentoxid**—*Arsenic anhydrid*—*Arsenic oxid*—As<sub>2</sub>O<sub>5</sub>—230—is obtained by heating arsenic acid to redness. It is a white, amorphous solid, which, when exposed to the air, slowly absorbs moisture. It is fusible at a dull red heat, and at a slightly higher temperature decomposes to As<sub>2</sub>O<sub>3</sub> and O. It dissolves slowly in H<sub>2</sub>O, forming arsenic acid, H<sub>3</sub>AsO<sub>4</sub>.

**Arsenic Acids.**—The oxyacids of arsenic form a series, corresponding to that of the oxyacids of phosphorus, except that the hyparsenious acid is unknown

**Arsenious Acid**— $\text{H}_3\text{AsO}_3$ —126—exists in aqueous solutions of the trioxid, although it has not been separated. Corresponding to it are important salts, called **arsenites**, which have the general formulæ  $\text{HM}'_2\text{AsO}_3$ ,  $\text{HM}''\text{AsO}_3$ ,  $\text{H}_4\text{M}''(\text{AsO}_3)_2$ .

**Arsenic Acid**—*Orthoarsenic acid*— $\text{H}_3\text{AsO}_4$ —142—is obtained by oxidizing  $\text{As}_2\text{O}_3$  with  $\text{HNO}_3$  in the presence of  $\text{H}_2\text{O}$ :  $\text{As}_2\text{O}_3 + 2\text{H}_2\text{O} + 2\text{HNO}_3 = 2\text{H}_3\text{AsO}_4 + \text{N}_2\text{O}_3$ . A similar oxidation is also effected by  $\text{Cl}$ , aqua regia, and other oxidants.

A syrupy, colorless, strongly acid solution is thus obtained, which, at  $15^\circ$  ( $59^\circ \text{F.}$ ) becomes semi-solid, from the formation of transparent crystals, containing 1 Aq. These crystals, which are very soluble and deliquescent, lose their Aq. at  $100^\circ$  ( $212^\circ \text{F.}$ ), and form a white, pasty mass composed of minute white, anhydrous needles. At higher temperatures it is converted into  $\text{H}_4\text{As}_2\text{O}_7$ ,  $\text{HASO}_3$ , and  $\text{As}_2\text{O}_5$ . In presence of nascent  $\text{H}$  it is decomposed into  $\text{H}_2\text{O}$  and  $\text{AsH}_3$ . It is reducible to  $\text{H}_3\text{AsO}_3$  by  $\text{SO}_2$ .

The action of  $\text{H}_2\text{S}$  upon acid solutions of arsenic acid, or of the arsenates, varies with the rapidity of the action, and the temperature at which it occurs. With a slow current of  $\text{H}_2\text{S}$ , at a low temperature, no precipitate is formed, and the solution remains colorless, under these conditions **sulphoxyarsenic acid**,  $\text{H}_3\text{AsO}_3\text{S}$  is formed:  $\text{H}_3\text{AsO}_4 + \text{H}_2\text{S} = \text{H}_3\text{AsSO}_3 + \text{H}_2\text{O}$ . By a further action of  $\text{H}_2\text{S}$ , arsenic pentasulphid is formed:  $2\text{H}_3\text{AsO}_3\text{S} + 3\text{H}_2\text{S} = \text{As}_2\text{S}_5 + 6\text{H}_2\text{O}$ . If the current of  $\text{H}_2\text{S}$  be very slow, the sulphoxyarsenic acid produced is decomposed according to the equation:  $2\text{H}_3\text{AsO}_3\text{S} = \text{As}_2\text{O}_3 + 3\text{H}_2\text{O} + \text{S}$ , and the precipitate then produced consists of a mixture of  $\text{As}_2\text{S}_3$ ,  $\text{As}_2\text{S}_5$  and  $\text{S}$ .

Like phosphoric acid, arsenic acid is tribasic; and the arsenates resemble the phosphates in composition, and in many of their chemical and physical properties.

**Pyroarsenic acid**— $\text{H}_4\text{As}_2\text{O}_7$ —266.—Arsenic acid, when heated to  $160^\circ$  ( $320^\circ \text{F.}$ ), is converted into compact masses of pyroarsenic acid:  $2\text{H}_3\text{AsO}_4 = \text{H}_4\text{As}_2\text{O}_7 + \text{H}_2\text{O}$ . It is very prone to revert to arsenic acid, by taking up water.

**Metarsenic acid**— $\text{HASO}_3$ —124.—At  $200$ – $206$  ( $392$ – $403^\circ \text{F.}$ )  $\text{H}_4\text{As}_2\text{O}_7$  gradually loses  $\text{H}_2\text{O}$  to form metarsenic acid:  $\text{H}_4\text{As}_2\text{O}_7 = 2\text{HASO}_3 + \text{H}_2\text{O}$ . It forms white, pearly crystals, which dissolve readily in  $\text{H}_2\text{O}$ , with regeneration of  $\text{H}_3\text{AsO}_4$ . It is monobasic.

**Compounds of Arsenic and Sulphur.**—**Arsenic disulphid**—*Red sulphid of arsenic*—*Realgar*—*Red orpiment*—*Ruby sulphur*—*Sandarach*— $\text{As}_2\text{S}_2$ —214—occurs in nature, in translucent, ruby-red crystals. It is also prepared by heating a mixture of  $\text{As}_2\text{O}_3$  and S. As so obtained it appears in brick-red masses.

It is fusible, insoluble in  $\text{H}_2\text{O}$ , but soluble in solutions of the alkaline sulphids, and in boiling solution of potassium hydrate.

**Arsenic trisulphid**—*Orpiment*—*Auripigmentum*—*Yellow sulphid of arsenic*—*King's yellow*— $\text{As}_2\text{S}_3$ —246—occurs in nature in brilliant golden yellow flakes. Obtained by passing  $\text{H}_2\text{S}$  through an acid solution of  $\text{As}_2\text{O}_3$ ; or by heating a mixture of As and S, or of  $\text{As}_2\text{O}_3$  and S in equivalent proportions.

When formed by precipitation, it is a lemon-yellow powder, or in orange-yellow, crystalline masses, when prepared by sublimation. Almost insoluble in cold  $\text{H}_2\text{O}$ , but sufficiently soluble in hot  $\text{H}_2\text{O}$  to communicate to it a distinct yellow color. By continued boiling with  $\text{H}_2\text{O}$  it is decomposed into  $\text{H}_2\text{S}$  and  $\text{As}_2\text{O}_3$ . Insoluble in dilute  $\text{HCl}$ ; but readily soluble in solutions of the alkaline hydrates, carbonates, and sulphids. It volatilizes when heated.

Nitric acid oxidizes it, forming  $\text{H}_3\text{AsO}_4$  and  $\text{H}_2\text{SO}_4$ . A mixture of  $\text{HCl}$  and potassium chlorate has the same effect. It corresponds in constitution to  $\text{As}_2\text{O}_3$ , and, like it, may be regarded as an anhydrid, for, although sulpharsenious acid,  $\text{H}_3\text{AsS}_3$ , has not been separated, the sulpharsenites, pyro- and meta-sulpharsenites are well-characterized compounds.

**Arsenic pentasulphid**— $\text{As}_2\text{S}_5$ —310—is formed by fusing a mixture of  $\text{As}_2\text{S}_3$  and S in proper proportions, and, by the prolonged action of  $\text{H}_2\text{S}$ , at low temperatures, upon solutions of the arsenates.

It is a yellow, fusible solid, capable of sublimation in absence of air. There exist well-defined sulpharsenates, pyro- and meta-sulpharsenates.

**Compounds of Arsenic with the Halogens.**—**Arsenic trifluorid**— $\text{AsF}_3$ —132.—A colorless, fuming liquid, boiling at  $63^\circ$  ( $145^\circ \text{F.}$ ), obtained by distilling a mixture of  $\text{As}_2\text{O}_3$ ,  $\text{H}_2\text{SO}_4$  and fluorspar. It attacks glass.

**Arsenic trichlorid**— $\text{AsCl}_3$ —181.5.—Obtained by distilling a mixture of  $\text{As}_2\text{O}_3$ ,  $\text{H}_2\text{SO}_4$  and  $\text{NaCl}$ , using a well-cooled receiver.

It is a colorless liquid, boils at  $134^\circ$  ( $273^\circ \text{F.}$ ), fumes when exposed to the air, and volatilizes readily at temperatures below its boiling-point. Its formation must be avoided in processes for the chemico-legal detection of arsenic, lest it be volatilized and lost. It is formed by the action of  $\text{HCl}$ , even when comparatively dilute, upon  $\text{As}_2\text{O}_3$  at the temperature of the water-bath:

but, if potassium chlorate be added, the trioxid is oxidized to arsenic acid, and the formation of the chlorid thus prevented. Arsenic trioxid, when fused with sodium nitrate, is converted into sodium arsenate, which is not volatile. If, however, small quantities of chlorids be present,  $\text{AsCl}_3$  is formed. It is highly poisonous.

**Arsenic tribromid— $\text{AsBr}_3$ —315.**—Obtained by adding powdered As to Br, and distilling the product at  $220^\circ$  ( $428^\circ \text{F.}$ ). A solid, colorless, crystalline body, fuses at  $20-25^\circ$  ( $68-77^\circ \text{F.}$ ), boils at  $220^\circ$  ( $428^\circ \text{F.}$ ), and is decomposed by  $\text{H}_2\text{O}$ .

**Arsenic triiodid—Arsenii iodidum, U. S.— $\text{AsI}_3$ —456.**—Formed by adding As to a solution of I in carbon disulphid; or by fusing together As and I in proper proportions. A brick-red solid, fusible and volatile. Soluble in a large quantity of  $\text{H}_2\text{O}$ . Decomposed by a small quantity of  $\text{H}_2\text{O}$  into HI,  $\text{As}_2\text{O}_3$ ,  $\text{H}_2\text{O}$  and a residue of  $\text{AsI}_3$ .

#### Action of Arsenical Compounds upon the Animal Economy.

The poisonous nature of many of the arsenical compounds has been known from remote antiquity, and it is probable that more murders have been committed by their use than by that of all other toxic substances combined. Even at the present time—withstanding the fact that, suspicion once aroused, the detection of arsenic in the dead body is certain and comparatively easy—criminal arsenical poisoning is still quite common, especially in rural districts.

The poison is usually taken by the mouth, but it has also been introduced by other channels: the skin, either uninjured or abraded; the rectum, vagina and male urethra. The forms in which it has been taken are: (1.) **Elementary arsenic**, which is not poisonous so long as it remains such. In contact with water, or with the saliva, however, it is converted into an oxid, which is then dissolved, and, being capable of absorption, produces the characteristic effects of the arsenical compounds. Fly-paper is coated with a paste containing As, a portion of which has been oxidized by the action of air and moisture. (2.) **Hydrogen arsenid**, the most actively poisonous of the inorganic compounds of arsenic, has been the cause of several accidental deaths, among others, that of the chemist Gehlen, who died in consequence of having inhaled the gas while experimenting with it. In other cases death has followed the inhalation of hydrogen, made from zinc and sulphuric acid contaminated with arsenic. (3.) **Arsenic trioxid** is the compound most frequently used by criminals. It has been given by every channel of entrance to the circulation: in some instances concealed with great art, in others merely held

in suspension by stirring in a transparent fluid, given to an intoxicated person. If the poison have been in quantity, and undissolved, it may be found in the stomach after death, in the form of eight-sided crystals, more or less worn by the action of the solvents with which it has come in contact.

The lethal dose is variable, death having occurred from two and one-half grains, and recovery having followed the taking of a dose of two ounces. It is more active when taken fasting than when taken on a full stomach, in which latter case all, or nearly all, the poison is frequently expelled by vomiting, before there has been time for the absorption of more than a small quantity.

(4.) **Potassium arsenite**, the active substance in "Fowler's solution," although largely used by the laity in malarial districts as an ague-cure, has, so far as the records show, produced but few cases of fatal poisoning.

(5.) **Sodium arsenite** is sometimes used to clean metal vessels, a practice whose natural results are exemplified in the death of an individual who drank beer from a pewter mug so cleaned; and in the serious illness of 340 children in an English institution, in which this material had been used for cleaning the water-boiler.

(6.) **Arsenic acid and arsenates**.—The acid itself has, so far as we know, been directly fatal to no one. The cases of death and illness, however, which have been put to the account of the red anilin dyes, are not due to them directly, but to arsenical residues remaining in them as the result of defective processes of manufacture.

(7.) **Sulphids of arsenic**.—Poisoning by these is generally due to the use of orpiment, introduced into articles of food as a coloring matter, by a combination of fraud and stupidity, in mistake for turmeric.

(8.) **The arsenical greens**.—Scheele's green, or cupric arsenite, and Schweinfurth green, or cupric aceto-metarsenite (the latter commonly known in the United States as Paris green, a name applied in Europe to one of the anilin pigments). These substances, although rarely administered with murderous intent, have been the cause of death in a great number of cases. Among suicides in the lower orders of the population in large cities, Paris green has been the favorite.

The arsenical pigments may also produce disastrous results by "accident;" by being incorporated in ornamental pieces of confectionery; by being used in the dyeing of textile fabrics, from which they may be easily rubbed off; from their use for the destruction of insects, and by being used in the manufacture of wall-paper. Many instances of chronic or subacute arsenical poisoning have resulted from inhabiting rooms hung with paper whose whites, reds, or greens were produced by arsenical pigments. From such paper the poison is disseminated in the atmosphere of the room in two ways: either as an impalpable powder, mechanically detached from the paper and floating in the

air, or by their decomposition, and the consequent diffusion of volatile arsenical compounds in the air.

The treatment in acute arsenical poisoning is the same, whatever may be the form in which the poison has been taken, if it have been taken by the mouth. The first indication is the removal of any unabsorbed poison from the alimentary canal. If vomiting have not occurred from the effects of the toxic, it should be induced by the administration of zinc sulphate, or by mechanical means. The stomach-pump should not be used unless the case is seen soon after the taking of the poison. When the stomach has been emptied, the chemical antidote is to be administered, with a view to the transformation, in the stomach, of any remaining arsenical compound into the insoluble, and therefore innocuous, ferrous arsenate. To prepare the antidote, a solution of ferrie sulphate, *Liq. ferri tersulphatis* (U. S.)=*Liq. ferri persulphatis* (Br.) is diluted with three volumes of water, and treated with aqua ammoniæ in slight excess. The precipitate formed is collected upon a muslin filter, and washed with water until the washings are nearly tasteless. The contents of the filter—*Ferri oxidum hydratum* (U. S.), *Ferri peroxidum humidum* (Br.) are to be given moist, in repeated doses of one to two teaspoonfuls, until an amount of the hydrate equal to 20 times the weight of white arsenic taken has been administered. Dialyzed iron may be given while the hydrate is in preparation, or when the materials for its preparation are not obtainable.

#### Precautions to be taken by the Physician in cases of suspected Poisoning.

It will rarely happen that in a case of suspected homicidal poisoning by arsenic, or by other poisons, the physician in charge will be willing or competent to conduct the chemical analysis, upon which, probably, the conviction or acquittal of the accused will mainly depend. Upon his knowledge and care, however, the success or futility of the chemist's labors depends in a great measure.

It is, as a rule, the physician who first suspects foul play: and, while it is undoubtedly his duty to avoid any public manifestation of his suspicion, it is as certainly his duty toward his patient and toward the community, to satisfy himself as to the truth or falsity of his suspicion by the application of a simple test to the excreta of the patient during life, the result of which may enable him to prevent a crime, or, failing that, take the first step toward the punishment of the criminal.

In a case in which, from the symptoms, the physician suspects poisoning by any substance, he should himself test the urine or

feces, or both, and govern his treatment and his actions toward the patient, and those surrounding the patient, by the results of his examination. Should the case terminate fatally, he should at once communicate his suspicions to the prosecuting officer, and require a post-mortem investigation, which should, if at all possible, be conducted in the presence of the chemist who is to conduct the analysis. For, be the physician as skilled as he may, there are odors and appearances, observable in many cases at the opening of the body, full of meaning to the toxicological chemist, which are ephemeral, and whose bearing upon the case is not readily recognized by those not thoroughly experienced.

Cases frequently arise in which it is impossible to bring the chemist upon the ground in time for the autopsy. In such cases the physician should remember that that portion of the poison remaining in the alimentary tract (we are speaking of true poisons) is but the residue of the dose in excess of that which has been necessary to produce death; and, if the processes of elimination have been active, there may remain no trace of the poison in the alimentary canal, while it still may be detectable in deeper-seated organs. The poison may also have been administered by another channel than the mouth, in which event it may not reach the stomach.

For these reasons it is not sufficient to send the stomach alone for analysis. The chemist should also receive the entire intestinal canal, at least one-half the liver, the spleen, one or both kidneys, a piece of muscular tissue from the leg, the brain, and any urine that may remain in the bladder. The intestinal canal should be removed and sent to the chemist *without having been opened*, and with ligatures, enclosing the contents, at the two ends of the stomach, and at the lower end of the intestine. The brain and alimentary canal are to be placed in separate jars, and the other viscera in another jar together; the urine in a vial by itself. All of these vessels are to be new and clean, and are to be closed by new corks, or by glass stoppers, or covers (not zinc screw-caps), which are then coated with paraffin (not sealing-wax), and so fastened with strings and seals, that it is impossible to open the vessels without cutting the strings, or breaking the seals. Any vomited matters are to be preserved. If the physician fail to observe these precautions, he has probably made the breach in the evidence through which the criminal will escape, and has at the outset defeated the aim of the analysis.

**Analytical Characters of the Arsenical Compounds.—Arsenious Compounds.**—(1.)  $\text{H}_2\text{S}$ , a yellow color in neutral or alkaline liquids; a yellow ppt. in acid liquids. The ppt. dissolves in solutions of the alkaline hydrates, carbonates, and sulphydrates; but is scarcely affected by  $\text{HCl}$ . Hot  $\text{HNO}_3$  decomposes it.

(2.)  $\text{AgNO}_3$ , in the presence of a little  $\text{NH}_4\text{HO}$ , gives a yellow ppt. This test is best applied by placing the neutral arsenical solution in a porcelain capsule, adding neutral solution of  $\text{AgNO}_3$ , and blowing upon it over the stopper of the  $\text{NH}_4\text{HO}$  bottle, moistened with that reagent.

(3.)  $\text{CuSO}_4$  under the same conditions as in (2) gives a yellowish-green ppt.

(4.) A small quantity of solid  $\text{As}_2\text{O}_3$  is placed in the point *a* of the tube, Fig. 32; above it, at *b*, a splinter of recently ignited charcoal; *b* is first heated to redness, then *a*; the vapor of  $\text{As}_2\text{O}_3$ , passing over the hot charcoal, is reduced, and elementary As is deposited at *c* in a metallic ring. The tube is then cut between *b* and *c*, the larger piece held with *d* uppermost and heated at *c*;

FIG. 32.

the deposit is volatilized, the odor of garlic is observed, and bright, octahedral crystals (Fig. 34), appear in the cool part of the tube.

(5.) **Reinsch test.**—The suspected liquid is acidulated with one-sixth its bulk of  $\text{HCl}$ . Strips of electrotype copper are immersed in the liquid, which is boiled. In the presence of an arsenious compound, a gray or bluish deposit is formed upon the  $\text{Cu}$ . A similar deposit is produced by other substances ( $\text{Bi}$ ,  $\text{Sb}$ ,  $\text{Hg}$ ). To complete the test the  $\text{Cu}$  is removed, washed, and dried between folds of filter-paper, without removing the deposit. The copper, with its adherent film, is rolled into a cylinder, and introduced into a dry piece of Bohemian tubing, about  $\frac{1}{4}$  inch in diameter and six inches long, which is held at the angle shown in Fig. 33 and heated at the point containing the copper. If the deposit consist of arsenic, a white deposit is formed at *a*, which contains brilliant specks, and, when examined with a magnifier, is found to consist of minute octahedral crystals, Fig. 34.

The advantages of this test are: it may be applied in the presence of organic matter, to the urine for instance; it is easily con-

ducted: and its positive results are not misleading, *if the test be carried to completion*. These advantages render it the most suitable method for the physician to use, *during the life of the patient*. It should not be used *after death* by the physician, as by

FIG. 33.

FIG. 34.

it copper is introduced into the substances under examination, which may subsequently interfere seriously with the analysis. The purity of the Cu and HCl must be proved by a blank testing before use. Reinsch's test is not as delicate as Marsh's, and it only reacts slowly and imperfectly when the arsenic is in the higher stage of oxidation, or in presence of oxidizing agents.

(B.) **Marsh's test** is based upon the formation of  $AsH_3$  when a reducible compound of arsenic is in presence of nascent H; and

FIG. 35.

the subsequent decomposition of the arsenical gas by heat, with separation of elementary arsenic.

The apparatus used (Fig. 35) consists of a glass generating vessel *a*, of about 150 c.c. capacity (5 fl. oz.), into whose upper opening

a funnel tube *c* is either ground, or fitted by a section of rubber tube. The lateral outlet is connected with a tube *d*, filled with fragments of calcium chlorid; which in turn connects with the Bohemian glass tube *gg*, which should be about 0.5 cent. in diameter, and about 80 cent. long. This tube is protected by a tube of wire gauze, within which it is adjusted in the furnace as shown in the figure. The other end of *gg* is bent downward, and dips into a solution of silver nitrate in the test-tube *f*.

The vessel *a* is first charged with about 25 grams ( $6\frac{1}{2}$  ) of pure granulated zinc, which has been in contact with a diluted solution of platinic chlorid for half an hour, and then washed. The apparatus is then connected in such a manner that all joints are gas-tight, and the funnel-tube *c* about half filled with  $\text{H}_2\text{SO}_4$ , diluted with an equal bulk of  $\text{H}_2\text{O}$ , and cooled. By opening the stopcock, the acid is brought in contact with the zinc in small quantities, in such a manner that during the entire testing bubbles of gas pass through *f*, at the rate of 60-80 per minute. After fifteen minutes the burner is lighted, and the heating continued, during evolution of gas from zinc and  $\text{H}_2\text{SO}_4$ , for an hour. At the end of that time, if no stain have formed in *g* beyond *e*, then zinc and acid may be considered pure and the suspected solution, prepared as described on page 137, introduced slowly through the funnel-tube.

If arsenic be present in the substance examined, a hair-brown or gray deposit is formed in the cool part of *g* beyond *e*. At the same time the contents of *f* are darkened if the amount of As present is so great that all the  $\text{AsH}_3$  produced is not decomposed in the heated portion of *gg*.

To distinguish the stains produced by arsenical compounds from the similar ones produced by antimony the following differences are noted:

#### *The Arsenical Stain.*

*First.*—Is farther removed from the heated portion of the tube, and, if small in quantity, is double—the first hair-brown, the second steel-gray.

*Second.*—Volatilizes readily when heated in an atmosphere of hydrogen, being deposited farther along in the tube. The escaping gas has the odor of garlic.

*Third.*—When cautiously heated in a current of oxygen, brilliant, white, octahedral crystals of arsenic trioxid are deposited farther along in the tube.

#### *The Antimonial Stain.*

*First.*—Is quite near the heated portion of the tube.

*Second.*—Requires a much higher temperature for its volatilization; fuses before volatilizing. Escaping gas has no alliaceous odor.

*Third.*—No crystals formed by heating in oxygen.

*The Arsenical Stain.*

*Fourth.*—Instantly soluble in solution of sodium hypochlorite.

*Fifth.*—Slowly dissolved by solution of ammonium sulphhydrate; more rapidly when warmed.

*Sixth.*—The solution obtained in 5 leaves, on evaporation over the water-bath, a bright yellow residue.

*Seventh.*—The residue obtained in 6 is soluble in aqua ammoniæ, but insoluble in hydrochloric acid.

*Eighth.*—Is soluble in warm nitric acid; the solution on evaporation yields a white residue, which turns brick-red when moistened with silver nitrate solution.

*Ninth.*—Is not dissolved by a solution of stannous chlorid.

*The Antimonial Stain.*

*Fourth.*—Insoluble in solution of sodium hypochlorite.

*Fifth.*—Dissolves quickly in solution of ammonium sulphhydrate.

*Sixth.*—The solution obtained in 5 leaves, on evaporation over the water-bath, an orange-red residue.

*Seventh.*—The residue obtained in 6 is insoluble in aqua ammoniæ, but soluble in hydrochloric acid.

*Eighth.*—Is soluble in warm nitric acid; the solution on evaporation yields a white residue, which is not colored when moistened with silver nitrate solution.

*Ninth.*—Dissolves slowly in solution of stannous chlorid.

If, however, the process described on p. 136 have been followed, there can be no antimony in the liquid which would contain arsenic, if present. The silver solution in *f* is tested for arsenious acid, by floating upon its surface a layer of diluted  $\text{NH}_4\text{HO}$  solution, which, in the presence of arsenic, produces a yellow (not brown) band, at the point of junction of the two liquids.

In place of bending the tube *gg'* downward, it may be bent upward and drawn out to a fine opening. If the escaping gas be then ignited, the heating of the tube being discontinued, a white deposit of  $\text{As}_2\text{O}_3$  may be collected on a glass surface held *above* the flame; or a brown deposit of elementary As upon a cold (porcelain) surface held *in* the flame.

In place of generating nascent hydrogen by the action of Zn on  $\text{H}_2\text{SO}_4$ , it may be produced by the decomposition of acidulated  $\text{H}_2\text{O}$  by the battery, in a Marsh apparatus especially modified for that purpose.

In another modification of the Marsh test the  $\text{AsH}_3$  is decomposed, not by passage through a red-hot tube, but by passing through a tube traversed by the spark from an induction coil.

(7.) **Fresenius' and von Babo's test.**—The sulphid, obtained in (1), is dried, and mixed with 12 parts of a *dry* mixture of 3 pts. sodium carbonate and 1 pt. potassium cyanid, and the mixture brought into a tube, drawn out to a fine opening, through which a slow current of  $\text{CO}_2$  is allowed to pass. The tube is then heated to redness at the point containing the mixture, when, if

arsenic be present, a gray deposit is formed at the constricted portion of the tube; which has the characters of the arsenical stain indicated on pp. 134, 135.

(8.) Place a small crystal of sodium sulphite in a solution of 0.3-0.4 gram of stannous chlorid in pure HCl, sp. gr. 1.13. Float the liquid to be tested on the surface of this mixture. If As be present a yellow band is formed at the junction of the two liquids, and gradually increases upward.

ARSENIC COMPOUNDS—(1.)  $H_2S$  does not form a ppt. in neutral or alkaline solutions. In acid solutions a yellow ppt., consisting either of  $As_2S_3$  or  $As_2S_5$ , or a mixture of the sulphids with free S, is formed only after prolonged passage of  $H_2S$  at the ordinary temperature, more rapidly at about 70 (158 F.).

(2.)  $AgNO_3$ , under the same conditions as with the arsenious compounds, produces a brick-red ppt. of silver arsenate.

(3.)  $CuSO_4$  under like circumstances produces a bluish-green ppt.

Arsenic compounds behave like arsenious compounds with the tests 4, 6 and 7 for the latter.

**Method of Analysis for Mineral Poisons.**—In cases of suspected poisoning a systematic course of analysis is to be followed by which the presence or absence of *all* the more usual poisons can be determined.

In the search for mineral poisons (see alkaloids), the first step is the destruction of organic matter. To this end the material to be examined, if liquid, is concentrated, and, if solid, is divided into small pieces and suspended in  $H_2O$ . About  $\frac{1}{10}$  the volume of concentrated HCl, and a small quantity of potassium chlorate are added, and the mixture allowed to stand 24 hours at the ordinary temperature, in a porcelain capsule covered by a glass plate. The contents of the capsule are then heated over the water-bath, while potassium chlorate, in small quantities, and, if necessary, HCl, are added from time to time, and the mixture is occasionally stirred, and lumps of solid matter crushed with a flattened glass rod, until the mass has a uniform light-yellow color. If the liquid smell strongly of Cl,  $CO_2$  is passed through it. When the odor of Cl has disappeared, the liquid is filtered, and the residue washed with hot water. If a deposit form on cooling, the liquid is again filtered. The clear filtrate and washings, if strongly acid, are *partially* neutralized with sodium carbonate, and treated with  $H_2S$ ; the gas being passed slowly through the liquid for about half an hour at a time, at intervals of 4-6 hours, during 3 days; the vessel being well corked during the intervals. The precipitate formed, which may contain Sn, As, Sb, Hg, Pb, Bi or Cu, is collected on a filter, and washed with  $H_2O$ , containing a small quantity of  $H_2S$ , until the washings fail to give the *faintest* cloudiness when boiled, acidulated with  $HNO_3$  and treated with silver nitrate.

Solution of ammonium sulphhydrate is added to the precipitate on the filter, which is then washed with water. The solution passing through may contain As, Sb, Sn and Cu; the residue on

the filter (A) may contain Hg, Pb, Bi and Cu. The solution is evaporated over the water-bath to dryness, and the residue moistened with fuming  $\text{HNO}_3$ , dried, moistened with  $\text{H}_2\text{O}$ , and dried several times, and then, after neutralization with caustic soda, fused with a mixture of sodium carbonate and nitrate, until it is colorless, or contains only a black, granular deposit, the heat being slowly increased. The cooled residue of fusion is dissolved in a small quantity of warm  $\text{H}_2\text{O}$ , and  $\text{CO}_2$  is passed through the solution, whether it be clear or cloudy. The solution, if not perfectly clear, is filtered. Any deposit retained by the filter (B) may contain Sn, Sb or Cu. The filtrate is strongly acidulated with  $\text{H}_2\text{SO}_4$ , and slowly evaporated and heated, with addition of more  $\text{H}_2\text{SO}_4$ , if necessary, until abundant white fumes are given off. The cooled residue, which may contain As, is dissolved in  $\text{H}_2\text{O}$ , and introduced into the Marsh apparatus when cold.

The residue B, if black, is dissolved in hot  $\text{HNO}_3$ , and the solution tested for Cu. If it be white, it is ignited, with the filter, in a porcelain crucible; fused with potassium cyanid; and washed with  $\text{H}_2\text{O}$ . The residue is extracted with warm  $\text{HCl}$ , and the solution tested for Sn. If any residue remain, it is extracted with  $\text{HCl}$ , to which a few drops of  $\text{HNO}_3$  have been added, and the solution tested for Sb.

The residue A, after washing, is boiled with  $\text{HNO}_3$ , diluted with  $\text{H}_2\text{O}$  and filtered. The filtrate is tested for Cu, Bi and Pb. The residue, if any, is tested for Hg and Pb.

### ANTIMONY.

*Symbol*—Sb (*Latin, stibium*)—*Atomic weight*=120—*Molecular weight*=240 (?)—*Sp. gr.*=6.175—*Fuses at* 450° (842° F.).

**Occurrence.**—Free in small quantity; principally in the trisulphid,  $\text{Sb}_2\text{S}_3$ .

**Preparation.**—The native sulphid (black, or crude antimony) is roasted, and then reduced, by heating with charcoal. The commercial antimony so obtained may be purified by fusing a mixture of antimony, 16 pts.: native sulphid of antimony, 1 pt.: and dry sodium carbonate, 2 pts. After cooling, the button is powdered, and fused with  $1\frac{1}{2}$  pts. sodium carbonate and  $1\frac{1}{2}$  ferrous sulphid. The antimony is again separated, powdered, and fused with sodium carbonate and a small quantity of sodium nitrate. Each fusion is maintained for an hour.

**Properties.**—*Physical.*—A bluish-gray, brittle solid, having a metallic lustre; readily crystallizable; tasteless and odorless; volatilizes at a red heat, and may be distilled in an atmosphere of H.

*Chemical.*—Is not altered by dry or moist air at ordinary temperatures. When sufficiently heated in air, it burns, with formation of  $\text{Sb}_2\text{O}_3$ , as a white, crystalline solid. It also combines directly with Cl, Br, I, S, and many metallic elements. It combines with H under the same circumstances as does As. Cold,

dilute  $\text{H}_2\text{SO}_4$  does not affect it; the hot, concentrated acid forms with it antimonyl sulphate,  $(\text{SbO})_2\text{SO}_4$  and  $\text{SO}_2$ . Hot  $\text{HCl}$  dissolves it, when finely divided, with evolution of  $\text{H}$ . It is readily oxidized by  $\text{HNO}_3$ , with formation of  $\text{H}_3\text{SbO}_4$  or  $\text{Sb}_2\text{O}_4$ . Aqua regia dissolves it as  $\text{SbCl}_3$ , or  $\text{SbCl}_5$ . Solutions of the alkaline hydrates do not act on it.

The element itself does not form salts with the oxyacids. There are, however, compounds, formed by the substitution of the group antimonyl ( $\text{SbO}$ ), for the basic hydrogen of those acids. (See tartar emetic.)

It enters into the composition of type metal, antifriction metals, and britannia metal.

**Hydrogen Antimonid**—*Antimoniuretted hydrogen*—*Stibamin*—*Stibonia*—*Stibin*— $\text{SbH}_3$ —123.—It has not been obtained in a condition of purity, but is produced, mixed with  $\text{H}$ , when a reducible compound of  $\text{Sb}$  is in presence of nascent  $\text{H}$ . It is obtained in larger amount, by decomposing an alloy of 400 parts of a 2% sodium amalgam, and 8 parts of freshly reduced, and dried  $\text{Sb}$ , by  $\text{H}_2\text{O}$ , in a current of  $\text{CO}_2$ .

It is a colorless, odorless, combustible gas, subject to the same decompositions as  $\text{AsH}_3$ ; from which it differs in being by no means as poisonous, and in its action upon silver nitrate solution. The arsenical gas acts upon the silver salt according to the equation:  $6\text{AgNO}_3 + \text{AsH}_3 + 3\text{H}_2\text{O} = 6\text{HNO}_3 + \text{H}_3\text{AsO}_3 + 3\text{Ag}_2$ , and the precipitate formed is elementary silver, while  $\text{H}_3\text{AsO}_3$  remains in the solution. In the case of  $\text{SbH}_3$  the reaction is  $3\text{AgNO}_3 + \text{SbH}_3 = 3\text{HNO}_3 + \text{SbAg}_3$ , all of the  $\text{Sb}$  being precipitated in the black silver antimonid.

**Compounds of Antimony and Oxygen**.—Three are known,  $\text{Sb}_2\text{O}_3$ ,  $\text{Sb}_2\text{O}_4$  and  $\text{Sb}_2\text{O}_5$ .

**Antimony trioxid**—*Antimonous anhydrid*—*Oxid of antimony*—*Antimonii oxidum* (**U. S.**; **Br.**)— $\text{Sb}_2\text{O}_3$ —288—occurs in nature; and is prepared artificially by decomposing the oxychlorid; or by heating  $\text{Sb}$  in air.

It is an amorphous, insoluble, tasteless, odorless powder; white at ordinary temperatures, but yellow when heated. It fuses readily, and may be distilled in absence of oxygen. Heated in air, it burns like tinder, and is converted into  $\text{Sb}_2\text{O}_4$ .

It is reduced, with separation of  $\text{Sb}$ , when heated with charcoal, or in  $\text{H}$ . It is also readily oxidized by  $\text{HNO}_3$ , or potassium permanganate. It dissolves in  $\text{HCl}$  as  $\text{SbCl}_3$ ; in Nordhausen sulphuric acid, from which solution brilliant crystalline plates of antimonyl pyrosulphate,  $(\text{SbO})_2\text{S}_2\text{O}_7$ , separate; and in solutions of tartaric acid, and of hydropotassic tartrate (see tartar emetic).

Boiling solutions of alkaline hydrates convert it into antimonious acid.

**Antimony pentoxid**—*Antimonie anhydrid*— $\text{Sb}_2\text{O}_5$ —320—is obtained by heating metantimonious acid to dull redness. It is an amorphous, tasteless, odorless, pale lemon-yellow colored solid; very sparingly soluble in water and in acids. At a red heat it is decomposed into  $\text{Sb}_2\text{O}_3$  and O.

**Antimony antimoniate**—*Intermediate oxid*—*Diantimonie tetroxid*— $\text{Sb}_2\text{O}_4$ —304—occurs in nature, and is formed when the oxids or hydrates of Sb are strongly heated, or when the lower stages of oxidation or the sulphids are oxidized by  $\text{HNO}_3$ , or by fusion with sodium nitrate. It is insoluble in  $\text{H}_2\text{O}$ ; but is decomposed by HCl, hydropotassic tartrate, and potash.

**Antimony Acids.**—The normal antimonious acid,  $\text{H}_3\text{SbO}_3$ , corresponding to  $\text{H}_3\text{PO}_3$ , is unknown; but the series of antimonious acids: ortho— $\text{H}_2\text{SbO}_4$ , pyro— $\text{H}_4\text{Sb}_2\text{O}_7$ , and meta— $\text{HSbO}_3$ , is complete, either in the form of salts, or in that of the free acids. There also exists, in its sodium salt, a derivative of the lacking antimonious acid: **metantimonious acid**,  $\text{HSbO}_2$ .

The compound sometimes used in medicine under the name *washed diaphoretic antimony* is potassium metantimonate, united with an excess of the pentoxid:  $2\text{KSbO}_3, \text{Sb}_2\text{O}_5$ . The hydropotassic pyroantimonate,  $\text{K}_2\text{H}_2\text{Sb}_2\text{O}_7, 6\text{Aq}$  is a valuable reagent for the sodium compounds. It is obtained by calcining a mixture of one part of antimony with four parts of potassium nitrate, and fusing the product with its own weight of potassium carbonate.

**Chlorids of Antimony.**—**Antimony trichlorid**—*Protochlorid* or *butter of antimony*— $\text{SbCl}_3$ —226.5—is obtained by passing dry Cl over an excess of  $\text{Sb}_2\text{S}_3$ ; by dissolving  $\text{Sb}_2\text{S}_3$  in HCl; or by distilling mixtures, either of  $\text{Sb}_2\text{S}_3$  and mercuric chlorid, or of Sb and mercuric chlorid, or of antimonyl pyrosulphate and sodium chlorid.

At low temperatures it is a solid, crystalline body; at the ordinary temperature a yellow, semi-solid mass, resembling butter; at  $73.2$  ( $164$  F.) it fuses to a yellow, oily liquid, which boils at  $223$  ( $433.4$  F.). Obtained by solution of  $\text{Sb}_2\text{S}_3$  in HCl of the usual strength, it forms a dark yellow solution, which, when concentrated to sp. gr. 1.47, constitutes the *Liq. Antimonii chloridi* (Br.).

It absorbs moisture from air, and is soluble in a small quantity of  $\text{H}_2\text{O}$ ; with a larger quantity it is decomposed, with precipitation of a white powder, **powder of Algaroth**, whose composition is  $\text{SbOCl}$  if cold  $\text{H}_2\text{O}$  be used, and  $\text{Sb}_2\text{O}_3\text{Cl}_2$  if the  $\text{H}_2\text{O}$  be boiling. In  $\text{H}_2\text{O}$  containing 15 per cent. or more HCl,  $\text{SbCl}_3$  is soluble without decomposition.

**Antimony pentachlorid**— $\text{SbCl}_5$ —297.5—is formed by the action of Cl, in excess, upon Sb or  $\text{SbCl}_3$ , and purified by distillation, in a current of Cl.

It is a fuming, colorless liquid, which solidifies at  $-20$  ( $-4$  F.), the solid fusing at  $-6$  ( $21.2$  F.). It absorbs moisture from air. With a small quantity of  $\text{H}_2\text{O}$ , and by evaporation over  $\text{H}_2\text{SO}_4$ , it forms a hydrate,  $\text{SbCl}_5 \cdot 4\text{H}_2\text{O}$ , which appears in transparent, deliquescent crystals. With more  $\text{H}_2\text{O}$ , a crystalline oxychlorid,  $\text{SbOCl}_3$ , is formed; and with a still greater quantity, a white precipitate of orthoantimonic acid,  $\text{H}_3\text{SbO}_4$ .

**Sulphids of Antimony.**—**Antimony trisulphid**—*Sesquisulphid of antimony*—*Black antimony*—**Antimonii sulphidum** (U. S.)—**Antimonium nigrum** (Br.)— $\text{Sb}_2\text{S}_3$ —336—is the chief ore of antimony; and is formed when  $\text{H}_2\text{S}$  is passed through a solution of tartar emetic.

The native sulphid is a steel-gray, crystalline solid; the artificial product, an orange-red, or brownish-red, amorphous powder. The crude antimony of commerce is in conical loaves, prepared by simple fusion of the native sulphid. It is soft, fusible, readily pulverized, and has a bright metallic lustre.

Heated in air, it is decomposed into  $\text{SO}_2$  and a brown, vitreous, more or less transparent mass, composed of varying proportions of oxid and oxysulphids, known as *crocus*, or *liver*, or *glass of antimony*.  $\text{Sb}_2\text{S}_3$  is an anhydrid, corresponding to which are salts known as *sulphantimonites*, having the general formula  $\text{M}_2\text{HSbS}_3$ . If an excess of  $\text{Sb}_2\text{S}_3$  be boiled with a solution of potash or soda, a liquid is obtained, which contains an alkaline sulphantimonite, and an excess of  $\text{Sb}_2\text{S}_3$ . If this solution be filtered, and decomposed by an acid while still hot, an orange-colored, amorphous precipitate is produced, which is the **antimonium sulphuratum** (U. S. ; Br.), and consists of a mixture, in varying proportions, of  $\text{Sb}_2\text{S}_3$  and  $\text{Sb}_2\text{O}_3$ . If, however, the solution be allowed to cool, a brown, voluminous, amorphous precipitate separates, which consists of antimony trisulphid and trioxid, potassium or sodium sulphid, and alkaline sulphantimonite in varying proportions; and is known as **Kermes mineral**. If now the solution from which the Kermes has been separated, be decomposed with  $\text{H}_2\text{SO}_4$ , a reddish-yellow substance separates, which is the **golden sulphuret of antimony**, and consists of a mixture of  $\text{Sb}_2\text{S}_3$  and  $\text{Sb}_2\text{S}_5$ . The precipitate obtained when  $\text{H}_2\text{S}$  acts upon a solution of an antimonial compound is, according to circumstances,  $\text{Sb}_2\text{S}_3$  or  $\text{Sb}_2\text{S}_5$ , mixed with free S. By the action of HCl on  $\text{Sb}_2\text{S}_3$ ,  $\text{H}_2\text{S}$  is produced.

**Antimony pentasulphid**— $\text{Sb}_2\text{S}_5$ —400—is obtained by decomposing an alkaline sulphantimonate by an acid. It is a dark orange-

red, amorphous powder, readily soluble in solutions of the alkalis, and alkaline sulphids, with which it forms **sulphantimonates**.

An oxysulphid,  $\text{Sb}_2\text{S}_3\text{O}_3$ , is obtained by the action of a solution of sodium hyposulphite upon  $\text{SbCl}_3$  or tartar emetic. It is a fine red powder, used as a pigment, and called **antimony cinnabar** or **antimony vermilion**.

**Action of Antimony Compounds on the Economy.**—The compounds of antimony are poisonous, and act with greater or less energy as they are more or less soluble. The compound which is most frequently the cause of antimonial poisoning is tartar emetic (q. v.), which has caused death in a dose of half a grain, although recovery has followed the ingestion of half an ounce in several instances. Indeed, the chances of recovery seem to be better with large, than with small doses, probably owing to the more rapid and complete removal of the poison by vomiting with large doses. Antimonials have been sometimes criminally administered in small and repeated doses, the victim dying of exhaustion. In such a case an examination of the urine will reveal the cause of the trouble.

If vomiting have not occurred in cases of acute antimonial poisoning it should be provoked by warm water, or the stomach should be evacuated by the pump. Tannin in some form (decoction of oak bark, cinchona, nutgalls, tea) should then be given, with a view to rendering any remaining poison insoluble.

Medicinal antimonials are very liable to contamination with arsenic.

**Analytical characters of Antimonial Compounds.**—(1.) With  $\text{H}_2\text{S}$  in acid solution, an orange-red ppt., soluble in  $\text{NH}_4\text{HS}$  and in hot  $\text{HCl}$ .

(2.) A strip of bright copper, suspended in a boiling solution of an Sb compound, acidulated with  $\text{HCl}$ , is coated with a blue-gray deposit. This deposit when dried (on the copper), and heated in a tube, open at both ends yields a white, *amorphous* sublimate (see No. 5, p. 132).

(3.) Antimonial compounds yield a deposit by Marsh's test, similar to that obtained with arsenical compounds, but differing in the particulars given above (see No. 6, p. 134).

If, in cases of suspected poisoning, the examination have been conducted as directed on p. 136, any Sb present is separated during the fusion with sodium nitrate and carbonate, and the subsequent solution and filtration, so completely that As and Sb cannot be mistaken for one another.

## IV.—BORON GROUP.

## BORON.

*Symbol*=**B**—*Atomic weight*=11—*Molecular weight*=22 (?)=*Isolated by Davy in 1807.*

Boron constitutes a group by itself; it is trivalent in all of its compounds; it forms but one oxid, which is the anhydrid of a tribasic acid; and it forms no compound with H.

It is separable in two allotropic modifications. **Amorphous boron** is prepared by decomposition of the oxid, by heating with metallic potassium or sodium. It is a greenish-brown powder; sparingly soluble in  $H_2O$ ; infusible, and capable of direct union with Cl, Br, O, S, and N.

**Crystallized boron** is produced when the oxid, chlorid or fluorid is reduced by Al. It crystallizes in quadratic prisms; more or less transparent, and varying in color from a faint yellow to deep garnet-red; very hard; sp. gr. 2.68. It burns when strongly heated in O, and readily in Cl; it also combines with N, which it is capable of removing from  $NH_3$  at a high temperature.

**Boron trioxid**—*Boric* or *boracic anhydrid*— $B_2O_3$ —70—is obtained by heating boric acid to redness in a platinum vessel. It is a transparent, glass-like mass, used in blowpipe analysis under the name **vitreous boric acid**.

**Boric Acids.**—**Boric acid**—*Boracic acid*—**Acidum boricum** (**U. S.**)— $H_3BO_3$ —62—occurs in nature; and is prepared by slowly decomposing a boiling, concentrated solution of borax, with an excess of  $H_2SO_4$ , and allowing the acid to crystallize.

It forms brilliant crystalline plates, unctuous to the touch; odorless; slightly bitter; soluble in 25 parts  $H_2O$  at 10° (50° F.); soluble in alcohol. Its solution reddens litmus, but turns turmeric paper brown. When its aqueous solution is distilled, a portion of the acid passes over.

Boric acid readily forms ethers with the alcohols. When heated with ethylic alcohol, **ethyl borate** is formed, which burns with a green flame. Heated with glycerin a soluble, neutral ether is formed, known as **boroglycerid**, and used as an antiseptic.

If  $H_3BO_3$  be heated for some time at 80° (176° F.), it loses  $H_2O$  and is converted into **metaboric acid**,  $HBO_2$ . If maintained at 100° (212° F.) for several days, it loses a further quantity of  $H_2O$ , and is converted into **tetraboric** or **pyroboric acid**,  $H_2B_4O_7$ , whose sodium salt is borax.

## V.—CARBON GROUP.

## CARBON—SILICON.

The elements of this group are bivalent or quadrivalent. The saturated oxid of each is the anhydrid of a dibasic acid. They are both combustibile, and each occurs in three allotropic forms.

## CARBON.

*Symbol*=C—*Atomic weight*=12—*Molecular weight*=24 (?).

**Occurrence.**—Free in its three allotropic forms: The diamond in octahedral crystals: in alluvial sand, clay, sandstone and conglomerate; graphite, in amorphous or imperfectly crystalline forms; amorphous, in the different varieties of anthracite and bituminous coal, jet, etc. In combination, it is very widely distributed in the so-called organic substances.

**Properties.**—**Diamond.**—The crystals of diamond, which is almost pure carbon, are usually colorless or yellowish, but may be blue, green, pink, brown or black. It is the hardest substance known, and the one which refracts light the most strongly. Its index of refraction is 2.47 to 2.75. It is very brittle; a bad conductor of heat and of electricity; sp. gr. 3.50 to 3.55. When very strongly heated in vacuo, it swells up, and is converted into a black mass, resembling coke.

**Graphite** is a form of carbon almost as pure as the diamond, capable of crystallizing in hexagonal plates; sp. gr. 2.2; dark gray in color; opaque; soft enough to be scratched by the nail; and a good conductor of electricity. It is also known as black lead or plumbago. It has been obtained artificially, by allowing molten cast-iron, containing an excess of carbon, to cool slowly, and dissolving the iron in HCl.

**Amorphous carbon** is met with in a great variety of forms, natural and artificial, in all of which it is black; sp. gr. 1.6–2.0; more or less porous; and a conductor of electricity.

**Anthracite** coal is hard and dense; it does not flame when burning; is difficult to kindle, but gives great heat with a suitable draught. It contains 80–90 per cent. of carbon. **Bituminous** coal differs from anthracite in that, when burning, it gives off gases, which produce a flame. Some varieties are quite soft, while others, such as jet, are hard enough to assume a high polish. It is usually compact in texture, and, very frequently, contains impressions of leaves, and other parts of plants. It contains about 75 per cent. of carbon.

**Charcoal**, *carbo ligni*, U. S., is obtained by burning woody fibre.

with an insufficient supply of air. It is brittle and sonorous: has the form of the wood from which it was obtained, and retains all the mineral matter present in the woody tissue. Its sp. gr. is about 1.57. It has the power of condensing within its pores odorous substances, and large quantities of gases; 99 volumes of ammonia, 55 of hydrogen sulphid, 9.25 of oxygen. This property is taken advantage of in a variety of ways. Its power of absorbing odorous bodies renders it valuable as a disinfecting, and filtering agent, and in the prevention of putrefaction and fermentation of certain liquids. The efficacy of charcoal as a filtering material is due also, in a great measure, to the oxidizing action of the oxygen condensed in its pores: indeed, if charcoal be boiled with dilute HCl, dried, and heated to redness, the oxidizing action of the oxygen, which it thus condenses, is very energetic.

**Lamp-black** is obtained by incomplete combustion of some resinous or fatty substance, or natural gas, the smoke or soot from which is directed into suitable condensing-chambers. It is a light, amorphous powder, and contains a notable quantity of oily and fatty material, from which it may be freed by heating in a covered vessel. It is used in the manufacture of printer's ink.

**Coke** is the substance remaining in gas-retorts, after the distillation of bituminous coal, in the manufacture of illuminating gas. It is a hard, grayish substance, usually very porous, dense, and sonorous. When iron retorts are used, a portion of the gaseous products are decomposed by contact with the hot iron surface, upon which there is then deposited a layer of very hard, compact, grayish carbon, which is a good conductor of electricity, and furnishes the best material for making the carbons of galvanic batteries and the points for the electric light. It does not form when gas is made in clay retorts.

**Animal charcoal** is obtained by calcining animal matters in closed vessels. If prepared from bones it is known as **bone-black**, *carbo animalis*, **U. S.**; if from ivory, **ivory black**. The latter is used as a pigment, the former as a decolorizing agent. Bones yield about 60 per cent. of bone-black, which contains, besides carbon, nitrogen and the phosphates and other mineral substances of the bones. It possesses in a remarkable degree the power of absorbing coloring matters. When its decolorizing power is lost by saturation with pigmentary bodies, it may be restored, although not completely, by calcination. For certain purposes purified animal charcoal, *i.e.*, freed from mineral matter, *carbo animalis purificatus*, **U. S.**, is required, and is obtained by extracting the commercial article with HCl, and washing it thoroughly. Its decolorizing power is diminished by this treatment. Animal charcoal has the power of removing from a solution certain crystalline substances, notably the alkaloids, and a

method has been suggested for separating these bodies from organic mixtures by its use.

All forms of carbon are insoluble in any known liquid.

*Chemical.*—All forms of C combine with O at high temperatures, with light and heat. The product of the union is carbon dioxide if the supply of air or O be sufficient; but if O be present in limited quantity, carbon monoxid is formed. The affinity of C for O renders it a valuable reducing agent. Many metallic oxids are reduced, when heated with C, and steam is decomposed when passed over red-hot C:  $\text{H}_2\text{O} + \text{C} = \text{CO} + \text{H}_2$ . At elevated temperatures C also combines directly with S, to form carbon disulphid. With H, carbon also combines directly, under the influence of the voltaic arc.

FOR COMPOUNDS OF CARBON SEE PAGE 222.

### SILICON.

*Symbol—Si—Atomic weight=28—Molecular weight=56 (?)—Discovered by Davy 1807—Name from silex=flint.*

Also known as **silicium**; occurs in three allotropic forms: **Amorphous silicon**, formed when silicon chlorid is passed over heated K or Na, is a dark brown powder, heavier than water. When heated in air, it burns with a bright flame to the dioxide. It dissolves in potash and in hydrofluoric acid, but is not attacked by other acids. **Graphitoid silicon** is obtained by fusing potassium fluosilicate with aluminium. It forms hexagonal plates, of sp. gr. 2.49, which do not burn when heated to whiteness in O, but may be oxidized at that temperature, by a mixture of potassium chlorate and nitrate. It dissolves slowly in alkaline solutions, but not in acids. **Crystallized silicon**, corresponding to the diamond, forms crystalline needles, which are only attacked by a mixture of nitric and hydrofluoric acids.

Silicon, although closely related to C, exists in nature in comparatively few compounds. It has been caused to form artificial combinations, however, which indicate its possible capacity to exist in substances, corresponding to those C compounds commonly known as organic, *e.g.*, **silicichloroform** and **silicibromoform**,  $\text{SiHCl}_3$  and  $\text{SiHBr}_3$ .

**Hydrogen silicid— $\text{SiH}_4$ ,—32—**is obtained as a colorless, insoluble, spontaneously inflammable gas, by passing the current of a galvanic battery of twelve cells through a solution of common salt, using a plate of aluminium, alloyed with silicon, as the positive electrode.

**Silicon chlorid— $\text{SiCl}_4$ ,—170—**a colorless, volatile liquid, having

an irritating odor; sp. gr. 1.52; boils at 59 ( $138^{\circ}.2$  F.); formed when Si is heated to redness in Cl.

**Silicic oxid**—*Silicic anhydrid*—*Silex*— $\text{SiO}_2$ —60—is the most important of the compounds of silicon. It exists in nature in the different varieties of quartz, and in the rocks and sands containing that mineral, in agate, carnelian, flint, etc. Its purest native form is rock crystal. Its hydrates occur in the opal, and in solution in natural waters. When crystallized, it is fusible with difficulty. When heated to redness with the alkaline carbonates it forms **silicates**, which solidify to glass-like masses, on cooling. It unites with  $\text{H}_2\text{O}$  to form a number of acid hydrates. The normal hydrate,  $\text{H}_4\text{SiO}_4$ , has not been isolated, although it probably exists in the solution, obtained by adding an excess of HCl to a solution of sodium silicate. A gelatinous hydrate, soluble in water and in acids and alkalies, is obtained by adding a small quantity of HCl to a concentrated solution of sodium silicate.

**Hydrofluosilicic acid**— $\text{H}_2\text{SiF}_6$ —144—is obtained in solution by passing the gas, disengaged by gently heating a mixture of equal parts of fluorspar and pounded glass, and 6 pts.  $\text{H}_2\text{SO}_4$ , through water; the disengagement tube being protected from moisture by a layer of mercury. It is used in analysis as a test for K and Na.

## VI. VANADIUM GROUP.

### VANADIUM—NIOBIUM—TANTALUM.

The elements of this group resemble those of the N group, but are usually quadrivalent.

**Vanadium**—**V**—51.3—a brilliant, crystalline metal; sp. gr. = 5.5; which forms a series of oxids similar to those of N. No salts of V are known, but salts of vanadyl (VO) are numerous, and are used in the manufacture of anilin black.

**Niobium**—**Nb**—94—a bright, steel-gray metal; sp. gr. 7.06; which burns in air to  $\text{Nb}_2\text{O}_5$  and in Cl to  $\text{NbCl}_5$ ; not attacked by acids.

**Tantalum**—**Ta**—182—closely resembles Nb in its chemical characters.

## VII. MOLYBDENUM GROUP.

### MOLYBDENUM—TUNGSTEN—OSMIUM.

The position of this group is doubtful; and it is probable that the lower oxids will be found to be basic in character: in which case the group should be transferred to the third class.

**Molybdenum**—**Mo**—95.5—a brittle white metal. The oxid  $\text{MoO}_3$ , *molybdic anhydrid*, combines with  $\text{H}_2\text{O}$  to form a number of acids; the ammonium salt of one of which is used as a reagent for  $\text{H}_3\text{PO}_4$ ; with which it forms a conjugate acid, *phosphomolybdic acid*, used as a reagent for the alkaloids.

**Tungsten**—**Wolfram**—**W**—183.6—a hard, brittle metal; sp. gr.

17.4. The oxid,  $\text{WO}_3$ , *tungstic anhydrid*, is a yellow powder, forming with  $\text{H}_2\text{O}$  several acid hydrates; one of which, *meta-tungstic acid*, is used as a test for the alkaloids, as are also the conjugate *silicotungstic* and *phosphotungstic acids*. Tissues impregnated with *sodium tungstate* are rendered unflammable.

**Osmium—Os—198.5**—occurs in combination with Ir in Pt ores; combustible and readily oxidized to  $\text{OsO}_4$ . This oxid, known as *osmic acid*, forms colorless crystals, soluble in  $\text{H}_2\text{O}$ , which give off intensely irritating vapors. It is used as a staining agent by histologists, and also in dental practice.

## CLASS III.—AMPHOTERIC ELEMENTS.

Elements whose Oxids Unite with Water, Some to Form Bases,  
Others to Form Acids. Which Form Oxysalts.

## I. GOLD GROUP.

## GOLD.

*Symbol* = **Au** (**AURUM**) — *Atomic weight* = 196.2 — *Molecular weight* = 392.4 (?) — *Sp. gr.* = 19.258–19.367 — *Fuses at* 1200° (2192° F.).

This, the only member of the group, forms two series of compounds; in one,  $\text{AuCl}$ , it is univalent; in the other,  $\text{AuCl}_3$ , trivalent. Its hydrate, auric acid,  $\text{Au}(\text{OH})_3$ , corresponds to the oxid  $\text{Au}_2\text{O}_3$ . Its oxysalts are unstable.

It is yellow or red by reflected light, green by transmitted light, reddish-purple when finely divided; not very tenacious; softer than silver; very malleable and ductile. It is not acted on by  $\text{H}_2\text{O}$  or air, at any temperature, nor by any single acid. It combines directly with Cl, Br, I, P, Sb, As, and Hg. It dissolves in nitromuriatic acid as auric chlorid. It is oxidized by alkalies in fusion on contact with air.

**Auric chlorid**—*Gold trichlorid*— $\text{AuCl}_3$ —302.7—obtained by dissolving Au in aqua regia, evaporating at 100° (212° F.), and purifying by crystallization from  $\text{H}_2\text{O}$ . Deliquescent, yellow prisms, very soluble in  $\text{H}_2\text{O}$ , alcohol and ether; readily decomposed, with separation of Au, by contact with P, or with reducing agents. Its solution, treated with the chlorids of tin, deposits a purple double stannate of Sn and Au, called "purple of cassius." With alkaline chlorids it forms double chlorids, chloraurates (*auri et sodii chloridum*, **U. S.**).

**Analytical Characters.**—(1.) With  $\text{H}_2\text{S}$ , from neutral or acid solution, a blackish-brown ppt. in the cold; insoluble in  $\text{HNO}_3$  and  $\text{HCl}$ ; soluble in aqua regia, and in yellow  $\text{NH}_4\text{HS}$ . (2.) With stannous chlorid and a little chlorin water, a purple-red ppt., insoluble in  $\text{HCl}$ . (3.) With ferrous sulphate a brown deposit, which assumes the lustre of gold when dried and burnished.

## II. IRON GROUP.

## CHROMIUM—MANGANESE—IRON.

The elements of this group form two series of compounds. In one they are bivalent, as in  $\text{Fe Cl}_2$  or  $\text{Mn SO}_4$ , while in the other

they are quadrivalent; but when quadrivalent, the atoms do not enter into combination singly, but grouped, two together, to form a hexavalent unit  $\left[ \begin{array}{c} \text{Fe} \equiv \\ | \\ \text{Fe} \equiv \end{array} \right]^{vi}$ , as in  $(\text{Fe}_2)^{vi}\text{Cl}_6$ ,  $(\text{Cr}_2)^{vi}\text{O}_3$ . They form several oxids; of which the oxid  $\text{MO}_3$  is an anhydrid, corresponding to which are acids and salts. Most of the other oxids are basic.

### CHROMIUM.

*Symbol* = Cr—*Atomic weight* = 52.06—*Molecular weight* = 104.12  
(?)—*Sp. gr.* = 6.8—*Discovered by* Vauquelin, 1797—*Name from*  $\chi\rho\acute{o}\mu\alpha$  = color.

Occurs in nature principally as chrome ironstone, a double oxid of Cr and Fe. The element is separated with difficulty by reduction of its oxid by charcoal, or of its chlorid by sodium. It is a hard, crystalline, almost infusible metal. Combines with O only at a red heat. It is not attacked by acids, except HCl; is readily attacked by alkalis.

**Chromic Oxid**—*Sesquioxid, or green oxid of chromium*— $\text{Cr}_2\text{O}_3$ —152.8—obtained, amorphous, by calcining a mixture of potassium dichromate and starch, or, crystallized, by heating neutral potassium chromate to redness in Cl.

It is green; insoluble in  $\text{H}_2\text{O}$ , acids, and alkalis; fusible with difficulty, and not decomposed by heat; not reduced by H. At a red heat in air, it combines with alkaline hydrates, and nitrates, to form chromates. It forms two series of salts, the terms of one of which are green, those of the other violet. The alkaline hydrates separate a bluish-green hydrate from solutions of the green salts, and a bluish-violet hydrate from those of the violet salts.

**Chromium green**, or emerald green, is a green hydrate, formed by decomposing a double borate of chromium and potassium by  $\text{H}_2\text{O}$ . It is used in the arts as a substitute for the arsenical greens, and is non-poisonous.

**Chromic Anhydrid**—**Acidum chromicum (U. S.)**— $\text{CrO}_3$ —100.4—is formed by decomposing a solution of potassium dichromate by excess of  $\text{H}_2\text{SO}_4$ , and crystallizing.

It crystallizes in deliquescent crimson prisms, very soluble in  $\text{H}_2\text{O}$ , and in dilute alcohol. It is a powerful oxidant, capable of igniting strong alcohol.

The true chromic acid has not been isolated, but salts are known which correspond to three acid hydrates:  $\text{H}_2\text{CrO}_4$  = chromic acid;  $\text{H}_2\text{Cr}_2\text{O}_7$  = dichromic acid; and  $\text{H}_2(\text{Cr}_3\text{O}_{10})$  = trichromic acid.

**Chlorids.**—Two chlorids and one oxychlorid of chromium are known. **Chromous chlorid**,  $\text{CrCl}_2$ , is a white solid, soluble, with

a blue color, in  $\text{H}_2\text{O}$ . **Chromic chlorid**,  $(\text{Cr}_2)\text{Cl}_6$ , forms large, red crystals, insoluble in  $\text{H}_2\text{O}$  when pure.

**Sulphates.**—A *violet* sulphate crystallizes in octahedra,  $(\text{Cr})_2(\text{SO}_4)_3 + 15 \text{ Aq.}$  and is very soluble in  $\text{H}_2\text{O}$ . At  $100^\circ$  it is converted into a *green* salt,  $(\text{Cr})_2(\text{SO}_4)_3 + 5 \text{ Aq.}$  soluble in alcohol; which, at higher temperatures, is converted into the red, insoluble, anhydrous salt. Chromic sulphate forms double sulphates, containing 24 Aq. with the alkaline sulphates. (See Alums.)

**Analytical Characters.**—**CHROMOUS SALTS.**—(1.) Potash, a brown ppt. (2.) Ammonium hydrate, greenish-white ppt. (3.) Alkaline sulphids, black ppt. (4.) Sodium phosphate, blue ppt.

**CHROMIC SALTS.**—(1.) Potash, green ppt.: an excess of precipitant forms a green solution, from which  $\text{Cr}_2\text{O}_3$  separates on boiling. (2.) Ammonium hydrate, greenish-gray ppt. (3.) Ammonium sulphhydrate, greenish ppt.

**CHROMATES.**—(1.)  $\text{H}_2\text{S}$  in acid solution, brownish color, changing to green. (2.) Ammonium sulphhydrate, greenish ppt. (3.) Barium chlorid, yellowish ppt. (4.) Silver nitrate, brownish-red ppt., soluble in  $\text{HNO}_3$  or  $\text{NH}_4\text{HO}$ . (5.) Lead acetate, yellow ppt., soluble in potash, insoluble in acetic acid.

**Action on the Economy.**—*Chromic anhydrid* oxidizes organic substances, and is used as a caustic.

The *chromates*, especially potassium dichromate (*q. v.*), are irritants, and have a distinctly poisonous action as well. Workmen handling the dichromate are liable to a form of chronic poisoning.

In acute chromium-poisoning, emetics, and subsequently magnesium carbonate in milk, are to be given.

## MANGANESE.

*Symbol* = **Mn**—*Atomic weight* = 54—*Molecular weight* = 108 (?)  
—*Sp. gr.* = 7.138–7.206.

Occurs chiefly in pyrolusite,  $\text{MnO}_2$ , hausmanite,  $\text{Mn}_3\text{O}_4$ , braunite,  $\text{Mn}_2\text{O}_3$ , and manganite,  $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . A hard, grayish, brittle metal; fusible with difficulty; obtained by reduction of its oxids by C at a white heat. It is not readily oxidized by cold, dry air; but is superficially oxidized when heated. It decomposes  $\text{H}_2\text{O}$ , liberating H; and dissolves in dilute acids.

**Oxids.**—Manganese forms six oxids or compounds representing them: **Manganous oxid**,  $\text{MnO}$ ; **manganoso-manganic oxid**,  $\text{Mn}_3\text{O}_4$ ; **manganic oxid**,  $\text{Mn}_2\text{O}_3$ ; **permanganic oxid**,  $\text{MnO}_2$ , and **permanganic anhydrid**,  $\text{Mn}_2\text{O}_7$ , are known free. **Manganic anhydrid**,  $\text{MnO}_3$ , has not been isolated.  $\text{MnO}$  and  $\text{Mn}_2\text{O}_3$  are basic;  $\text{Mn}_3\text{O}_4$

and  $\text{MnO}_2$  are indifferent oxids; and  $\text{MnO}_3$  and  $\text{Mn}_2\text{O}_7$  are anhydrides, corresponding to the manganates and permanganates.

**Permanganic Oxid**—*Manganese dioxide, or black oxid*—**Man-gani oxidum nigrum (U. S.)—Manganesii ox. nig. (Br.)— $\text{MnO}_2$** —86—exists in nature as pyrolusite, the principal ore of manganese, in steel gray, or brownish-black, imperfectly crystalline masses.

At a red heat it loses 12 per cent. of O:  $3\text{MnO}_2 = \text{Mn}_3\text{O}_4 + \text{O}_2$ ; and, at a white heat, a further quantity of O is given off:  $2\text{Mn}_3\text{O}_4 = 6\text{MnO} + \text{O}_2$ . Heated with  $\text{H}_2\text{SO}_4$ , it gives off O, and forms manganous sulphate:  $2\text{MnO}_2 + 2\text{H}_2\text{SO}_4 = 2\text{MnSO}_4 + 2\text{H}_2\text{O} + \text{O}_2$ . With HCl it yields manganous chlorid,  $\text{H}_2\text{O}$  and Cl:  $\text{MnO}_2 + 4\text{HCl} = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2$ . It is not acted on by  $\text{HNO}_3$ .

**Chlorids.**—Two chlorids of Mn are known: manganous chlorid,  $\text{MnCl}_2$ , a pink, deliquescent, soluble salt, occurring, mixed with ferric chlorid, in the waste liquid of the preparation of Cl; and manganic chlorid,  $\text{Mn}_2\text{Cl}_6$ .

**Salts of Manganese.**—Manganese forms two series of salts: **Manganous salts**, containing  $\text{Mn}^{+2}$ ; and **manganic salts**, containing  $(\text{Mn}_2)^{+4}$ ; the former are colorless or pink, and soluble in water; the latter are unstable.

**Manganous Sulphate**—**Man-gani sulphas (U.S.)— $\text{MnSO}_4 \cdot n\text{Aq}$** —150 +  $n$ 18—is formed by the action of  $\text{H}_2\text{SO}_4$  on  $\text{MnO}_2$ . Below 6° (42.8 F.) it crystallizes with 7 Aq. and is isomorphous with ferrous sulphate; between 7–20° (44.6–68 F.) it forms crystals with 5 Aq. and is isomorphous with cupric sulphate; between 20–30° (68–86 F.) it crystallizes with 4 Aq. It is rose-colored, darker as the proportion of Aq. increases, soluble in  $\text{H}_2\text{O}$ , insoluble in alcohol. With the alkaline sulphates it forms double salts, with 6 Aq.

**Analytical Characters.**—**MANGANOUS.**—(1.) Potash, white ppt., turning brown. (2.) Alkaline carbonates, white ppts. (3.) Ammonium sulphhydrate, flesh-colored ppt., soluble in acids, sparingly soluble in excess of precipitant. (4.) Potassium ferrocyanid, faintly reddish-white ppt., in neutral solution; soluble in HCl. (5.) Potassium cyanid, rose-colored ppt., forming brown solution with excess.

**MANGANIC.**—(1.)  $\text{H}_2\text{S}$ , ppt. of sulphur. (2.) Ammonium sulphhydrate, flesh-colored ppt. (3.) Potassium ferrocyanid, greenish ppt. (4.) Potassium ferricyanid, brown ppt. (5.) Potassium cyanid, light brown ppt.

**MANGANATES**—are green salts, whose solutions are only stable in presence of excess of alkali, and turn brown when diluted and acidulated.

**PERMANGANATES**—form red solutions, which are decolorized by  $\text{SO}_2$ , other reducing agents, and many organic substances.

## IRON.

*Symbol* = Fe (**FERRUM**)—*Atomic weight* = 55.9—*Molecular weight* = 111.8 (?)—*Sp. gr.* = 7.25–7.9—*Fuses at* 1600° (2912° F.)—*Name from the Saxon*, *iren*.

**Occurrence.**—Free, in small quantity only, in platinum ores and meteorites. As  $\text{Fe}_2\text{O}_3$  in *red hematite* and *specular iron*; as hydrates of  $\text{Fe}_2\text{O}_3$  in *brown hematite* and *oolitic iron*; as  $\text{Fe}_3\text{O}_4$  in *magnetic iron*; as  $\text{FeCO}_3$  in *spathic iron*, *clay ironstone* and *bog ore*; and as  $\text{FeS}_2$  in *pyrites*. It is also a constituent of most soils and clays, exists in many mineral waters, and in the red blood pigment of animals.

**Preparation.**—In working the ores, reduction is first effected in a *blast-furnace*, into which alternate layers of ore, coal and limestone are fed from the top, while air is forced in from below. In the lower part of the furnace  $\text{CO}_2$  is produced, at the expense of the coal; higher up it is reduced by the incandescent fuel to CO, which, at a still higher point, reduces the ore. The fused metal, so liberated, collects at the lowest point, under a layer of *slag*; and is drawn off to be cast as *pig iron*. This product is then purified, by burning out impurities, in the process known as *puddling*.

*Pure iron* is prepared by reduction of ferrous chlorid, or of ferric oxid, by H at a temperature approaching redness.

**Varieties.**—*Cast iron* is a brittle, white or gray, crystalline metal, consisting of Fe 89–90%; C 1–4.5%; and Si, P, S, and Mn. As *pig iron*, it is the product of the blast-furnace.

*Wrought, or bar iron*, is a fibrous, tough metal, freed in part from the impurities of cast iron, by *refining* and *puddling*.

*Steel* is Fe combined with a quantity of C, less than that existing in cast iron, and greater than that in bar iron. It is prepared by *cementation*: which consists in causing bar iron to combine with C; or by the *Bessemer method*; which, as now used, consists in burning the C out of molten cast iron, to which the proper proportion of C is then added in the shape of *spiegel Eisen*, an iron rich in Mn and C.

The purest forms of commercial iron are those used in piano-strings, the teeth of carding machines, and electro-magnets: known as *soft iron*.

*Reduced iron*—**Ferrum reductum (U. S.)**—**Fer. redactum (Br.)**—is Fe, more or less mixed with  $\text{Fe}_2\text{O}_3$  and  $\text{Fe}_3\text{O}_4$ , obtained by heating  $\text{Fe}_2\text{O}_3$  in H.

**Properties.**—*Physical.*—Pure iron is silver-white; quite soft; crystallizes in cubes or octahedra. *Wrought iron* is gray, hard, very tenacious, fibrous, quite malleable and ductile, capable of

being welded, highly magnetic, but only temporarily so. *Steel* is gray, very hard and brittle if *tempered*, soft and tenacious if not, permanently magnetic.

*Chemical.*—Iron is not altered by dry air at the ordinary temperature. At a red heat it is oxidized. In damp air it is converted into a hydrate, *iron rust*. *Tinplate* is sheet iron, coated with tin; *galvanized iron* is coated with zinc, to preserve it from the action of damp air.

Iron unites directly with Cl, Br, I, S, N, P, As, and Sb. It dissolves in HCl as ferrous chlorid, while H is liberated. Heated with strong  $\text{H}_2\text{SO}_4$ , it gives off  $\text{SO}_2$ ; with dilute  $\text{H}_2\text{SO}_4$ , H is given off and ferrous sulphate formed. Dilute  $\text{HNO}_3$  dissolves Fe, but the concentrated acid renders it *passive*, when it is not dissolved by either concentrated or dilute  $\text{HNO}_3$ , until the passive condition is destroyed by contact with Pt, Ag or Cu, or by heating to  $40^\circ$  ( $104^\circ$  F.).

**Compounds of Iron.—Oxids.**—Three oxids of iron exist free:  $\text{FeO}$ ;  $\text{Fe}_2\text{O}_3$ ;  $\text{Fe}_3\text{O}_4$ .

**Ferrous Oxid**—*Protoxid of iron*— $\text{FeO}$ —71.9—is formed by heating  $\text{Fe}_2\text{O}_3$  in CO or  $\text{CO}_2$ .

**Ferric Oxid**—*Sesquioxid or peroxid of iron*—*Colcothar*—*Jeweller's rouge*—*Venetian red*— $\text{Fe}_2\text{O}_3$ —159.8—occurs in nature (see above); and is formed when ferrous sulphate is strongly heated, as in the manufacture of pyrosulphuric acid. It is a reddish, amorphous solid, is a weak base, and is decomposed at a white heat into O and  $\text{Fe}_3\text{O}_4$ .

**Magnetic Oxid**—*Black oxid*—*Ferri oxidum magneticum* (Br.)— $\text{Fe}_3\text{O}_4$ —231.7—is the natural loadstone, and is formed by the action of air, or steam, upon iron at high temperatures. It is probably a compound of ferrous and ferric oxids ( $\text{FeO}$ ,  $\text{Fe}_2\text{O}_3$ ), as acids produce with it mixtures of ferrous and ferric salts.

**Hydrates.—Ferrous.**—When a solution of a ferrous salt is decomposed by an alkaline hydrate, a greenish-white hydrate,  $\text{FeH}_2\text{O}_2$ , is deposited; which rapidly absorbs O from the air, with formation of ferric hydrate.

**Ferric.**—When an alkali is added to a solution of a ferric salt, a brown, gelatinous precipitate is formed, which is the normal ferric hydrate,  $(\text{Fe}_{\frac{1}{2}} \text{H}_2\text{O}_6)$ —*Ferri peroxidum hydratum* (U. S.); *Fer. perox. humidum* (Br.). It is not formed in the presence of fixed organic acids, or of sugar in sufficient quantity. If preserved under  $\text{H}_2\text{O}$ , it is partly oxidized, forming an oxyhydrate which is incapable of forming ferrous arsenate with  $\text{As}_2\text{O}_3$ .

If the hydrate,  $(\text{Fe}_2)\text{H}_2\text{O}_6$ , be dried at  $100^\circ$  ( $212^\circ$  F.), it loses  $2\text{H}_2\text{O}$ , and is converted into  $(\text{Fe}_2)\text{O}_2$ ,  $\text{H}_2\text{O}_2$ , which is the *Ferri peroxidum hydratum* (Br.).

If the normal hydrate be dried *in vacuo*, it is converted into  $(\text{Fe}_2)_2\text{H}_6\text{O}_9$ , and this, when boiled for some hours with  $\text{H}_2\text{O}$ , is converted into the colloid or modified hydrate  $(\text{Fe}_2)\text{H}_2\text{O}_4$  (?), which is brick-red in color, almost insoluble in  $\text{HNO}_3$  and  $\text{HCl}$ , gives no Prussian blue reaction, and forms a turbid solution with acetic acid. If recently precipitated ferric hydrate be dissolved in solution of ferric chlorid or acetate, and subjected to dialysis, almost all the acid passes out, leaving in the dialyzer a dark red solution, which probably contains this colloid hydrate, and which is instantly coagulated by a trace of  $\text{H}_2\text{SO}_4$ , by alkalies, many salts, and by heat; **dialyzed iron**.

**Ferric Acid.**— $\text{H}_2\text{Fe}_2\text{O}_4$ .—Neither the free acid nor the oxid,  $\text{FeO}_3$ , are known in the free state; the **ferrates**, however, of Na, K, Ba, Sr, and Ca are known.

**Sulphids.**—**Ferrous Sulphid**—*Protosulphid of iron*— $\text{FeS}$ —87.9—is formed:

(1) By heating a mixture of finely divided Fe and S to redness; (2) by pressing roll-sulphur on white-hot iron; (3) in a hydrated condition,  $\text{FeS}$ ,  $\text{H}_2\text{O}$ , by treating a solution of a ferrous salt with an alkaline sulphhydrate.

The dry sulphid is a brownish, brittle, magnetic solid, insoluble in  $\text{H}_2\text{O}$ , soluble in acids with evolution of  $\text{H}_2\text{S}$ . The hydrate is a black powder, which absorbs O from the air, turning yellow, by formation of  $\text{Fe}_2\text{O}_3$ , and liberation of S. It occurs in the *faeces* of persons taking chalybeate waters or preparations of iron.

**Ferric Sulphid**—*Sesquisulphid*— $\text{Fe}_2\text{S}_3$ —207.8—occurs in nature in *copper pyrites*, and is formed when the disulphid is heated to redness.

**Ferric Disulphid**— $\text{FeS}_2$ —119.9—occurs in the *white* and *yellow Martial pyrites*, used in the manufacture of  $\text{H}_2\text{SO}_4$ . When heated in air, it is decomposed into  $\text{SO}_2$  and *magnetic pyrites*:  $3\text{FeS}_2 + 2\text{O}_2 = \text{Fe}_3\text{S}_4 + 2\text{SO}_2$ .

**Chlorids.**—**Ferrous Chlorid**—*Protochlorid*— $\text{FeCl}_2$ —129.9—is produced: (1) by passing dry  $\text{HCl}$  over red-hot Fe; (2) by heating ferric chlorid in H; (3), as a hydrate,  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ , by dissolving Fe in  $\text{HCl}$ .

The anhydrous compound is a yellow, crystalline, volatile, and very soluble solid. The hydrated is in greenish, oblique rhombic prisms, deliquescent and very soluble in  $\text{H}_2\text{O}$  and alcohol. When heated in air it is converted into ferric chlorid, and an oxychlorid.

**Ferric Chlorid**—*Sesquichlorid*—*Perchlorid*—**Ferri chloridum** (U. S.)— $\text{Fe}_2\text{Cl}_6$ —324.8—is produced, in the anhydrous form, by heating Fe in  $\text{Cl}$ . As a hydrate,  $\text{Fe}_2\text{Cl}_6 \cdot 4\text{H}_2\text{O}$ , or  $\text{Fe}_2\text{Cl}_6 \cdot 6\text{H}_2\text{O}$ , it is formed: (1) by solution of the anhydrous compound; (2) by dissolving Fe in aqua regia; (3) by dissolving ferric hydrate in

HCl; (4) by the action of Cl or of  $\text{HNO}_3$  on solution of ferrous chlorid. It is by the last method that the pharmaceutical product is obtained.

The anhydrous compound forms reddish-violet, crystalline plates, very deliquescent. The hydrates form yellow, nodular, imperfectly crystalline masses, or rhombic plates, very soluble in  $\text{H}_2\text{O}$ , soluble in alcohol and ether. In solution, it is converted into  $\text{FeCl}_2$  by reducing agents. The **Liq. ferri chloridi** (**U. S.**) = **Liq. fer. perchloridi** (**Br.**) is an aqueous solution of this compound, containing excess of acid. The **Tinct. fer. chlor.** (**U. S.**) and **Tinct. fer. perchl.** (**Br.**) are the solution, diluted with alcohol; and contain ethyl chlorid and ferrous chlorid.

**Bromids.**—**Ferrous Bromid**— $\text{FeBr}_2$ —215.9—is formed by the action of Br on excess of Fe, in presence of  $\text{H}_2\text{O}$ .

**Ferric Bromid**— $\text{Fe}_2\text{Br}_6$ —591.8—is prepared by the action of excess of Br on Fe.

**Iodids.**—**Ferrous Iodid**—**Ferri iodidum** (**U. S.**; **Br.**)— $\text{FeI}_2$ —309.9—is obtained, with  $4\text{H}_2\text{O}$ , by the action of I upon excess of Fe in the presence of warm  $\text{H}_2\text{O}$ . When anhydrous, it is a white powder; hydrated, it is in green crystals. In air it is rapidly decomposed, more slowly in the presence of sugar.

**Ferric Iodid**— $\text{Fe}_2\text{I}_6$ —873.8—is formed by the action of excess of I on Fe.

**Salts of Iron.**—**Sulphates.**—**Ferrous Sulphate**—*Protosulphate*—**Green vitriol**—**Copperas**—**Ferri sulphas** (**U. S.**; **Br.**)— $\text{FeSO}_4$ —7 **Aq.**—151.9 + 126—is formed: (1) by oxidation of the sulphid,  $\text{FeS}_2$ , formed in the manufacture of  $\text{H}_2\text{SO}_4$ ; (2) by dissolving Fe in dilute  $\text{H}_2\text{SO}_4$ .

It forms green, efflorescent, oblique rhombic prisms, quite soluble in  $\text{H}_2\text{O}$ , insoluble in alcohol. It loses 6 **Aq.** at  $100^\circ$  ( $212^\circ \text{F.}$ ) (**Ferr. sulph. exsiccatus**, **U. S.**); and the last **Aq.** at about  $300^\circ$  ( $572^\circ \text{F.}$ ). At a red heat it is decomposed into  $\text{Fe}_2\text{O}_3$ ,  $\text{SO}_2$  and  $\text{SO}_3$ . By exposure to air it is gradually converted into a basic ferric sulphate,  $(\text{Fe}_2)(\text{SO}_4)_3 \cdot 5\text{Fe}_2\text{O}_3$ .

**Ferric Sulphates** are quite numerous, and are formed by oxidation of ferrous sulphate under different conditions. The normal sulphate,  $(\text{Fe}_2)(\text{SO}_4)_3$ , is formed by treating solution of  $\text{FeSO}_4$  with  $\text{HNO}_3$ , and evaporating, after addition of one molecule of  $\text{H}_2\text{SO}_4$  for each two molecules of  $\text{FeSO}_4$ . The **Liq. fer. tersulphatis** (**U. S.**) contains this salt. It is a yellowish-white, amorphous solid.

Of the many basic ferric sulphates, the only one of medical interest is **Monsel's salt**,  $5(\text{Fe}_2)(\text{SO}_4)_3 + 4\text{Fe}_2\text{O}_3$ , which exists in the **Liq. ferri subsulphatis** (**U. S.**) and **Liq. fer. persulphatis** (**Br.**). Its solution is decolorized, and forms a white deposit with excess of  $\text{H}_2\text{SO}_4$ .

**Nitrates.**—**Ferrous Nitrate**— $\text{Fe}(\text{NO}_3)_2$ —179.9—a greenish, unstable salt, formed by double decomposition between barium nitrate and ferrous sulphate; or by the action of  $\text{HNO}_3$  on  $\text{FeS}$ .

**Ferric Nitrates.**—The *normal nitrate*— $(\text{Fe}_2)(\text{NO}_3)_6$ —483.8—is obtained in solution by dissolving Fe in  $\text{HNO}_3$  of sp. gr. 1.115; or by dissolving ferric hydrate in  $\text{HNO}_3$ . It therefore exists in the *Liq. ferri nitratis* (U. S.). It crystallizes in rhombic prisms with 18 Aq, or in cubes with 12 Aq.

Several basic nitrates are known, all of which are uncrystallizable, and by their presence (as when Fe is dissolved in  $\text{HNO}_3$  to saturation) prevent the crystallization of the normal salt.

**Phosphates.**—**Triferrous Phosphate**— $\text{Fe}_3(\text{PO}_4)_2$ —357.7.—A white precipitate, formed by adding disodic phosphate to a solution of a ferrous salt, in presence of sodium acetate. By exposure to air it turns blue; a part being converted into ferric phosphate. The *ferri phosphas* (Br.) is such a mixture of the two salts. It is insoluble in  $\text{H}_2\text{O}$ ; sparingly soluble in  $\text{H}_2\text{O}$  containing carbonic or acetic acid.

It is probably this phosphate, capable of turning blue, which sometimes occurs in the lungs in phthisis, in blue pus, and in long-buried bones.

**Ferric Phosphate**— $(\text{Fe}_2)(\text{PO}_4)_2$ —301.8—is produced by the action of an alkaline phosphate on ferric chlorid. It is soluble in  $\text{HCl}$ ,  $\text{HNO}_3$ , citric and tartaric acids, insoluble in phosphoric acid and in solution of hydrosodic phosphate. The *ferri phosphas* (U. S.) is a compound, or mixture of this salt with disodic citrate, which is soluble in water.

There exist quite a number of basic ferric phosphates.

**Ferric Pyrophosphate**— $(\text{Fe}_2)_2(\text{P}_2\text{O}_7)_3$ —745.6—is precipitated by decomposition of a solution of a ferric compound by sodium pyrophosphate; an excess of the Na salt dissolves the precipitate when warmed, and, on evaporation, leaves scales of a double salt,  $(\text{Fe}_2)_2(\text{P}_2\text{O}_7)_3, \text{Na}_4(\text{P}_2\text{O}_7)_2 + 20 \text{ Aq}$ .

The *ferri pyrophosphas* (U. S.) is a mixture of ferric pyrophosphate, trisodic citrate, and ferric citrate.

**Acetates.**—**Ferrous Acetate**— $\text{Fe}(\text{C}_2\text{H}_3\text{O}_2)_2$ —173.9—is formed by decomposition of ferrous sulphate by calcium acetate, in soluble, silky needles.

**Ferric Acetates.**—The *normal salt*,  $(\text{Fe}_2)(\text{C}_2\text{H}_3\text{O}_2)_6$ , is obtained by adding slight excess of ferric sulphate to lead acetate, and decanting after twenty-four hours. It is dark red, uncrystallizable, very soluble in alcohol, and in  $\text{H}_2\text{O}$ . If its solution be heated it darkens suddenly, gives off acetic acid, and contains a basic acetate. When boiled, it loses all its acetic acid, and deposits ferric hydrate. When heated in closed vessels to  $100^\circ$  ( $212^\circ \text{ F.}$ ), and treated with a trace of mineral acid, it deposits the modified ferric hydrate.

**Ferrous Carbonate**— $\text{FeCO}_3$ —115.9—occurs as an ore of iron, and is obtained, in a hydrated form, by adding an alkaline carbonate to a ferrous salt. It is a greenish, amorphous powder, which on exposure to air, turns red by formation of ferric hydrate; a change which is retarded by the presence of sugar, hence the addition of that substance in the *ferri carbonas saccharatus* (U. S.; Br.). It is insoluble in pure  $\text{H}_2\text{O}$ , but soluble in  $\text{H}_2\text{O}$  containing carbonic acid, probably as ferrous bicarbonate,  $\text{H}_2\text{Fe}(\text{CO}_3)_2$ , in which form it occurs in chalybeate waters.

**Ferrous Lactate**—*Ferri lactas* (U. S.)— $\text{Fe}(\text{C}_3\text{H}_5\text{O}_3)_2 + 3\text{Aq}$ —233.9 + 54—is formed when iron filings are dissolved in lactic acid. It crystallizes in greenish-yellow needles; soluble in  $\text{H}_2\text{O}$ ; insoluble in alcohol; permanent in air when dry.

**Ferrous Oxalate**—*Ferri oxalas* (U. S.)— $\text{FeC}_2\text{O}_4 + \text{Aq}$ —143.9 + 36—is a yellow, crystalline powder; sparingly soluble in  $\text{H}_2\text{O}$ ; formed by dissolving iron filings in solution of oxalic acid.

**Tartrates**—**Ferrous Tartrate**— $\text{FeC}_4\text{H}_4\text{O}_6 + 2\text{Aq}$ —203.9 + 36.—A white, crystalline powder; formed by dissolving Fe in hot concentrated solution of tartaric acid.

**Ferric Tartrate**— $\text{Fe}_2(\text{C}_4\text{H}_4\text{O}_6)_3 + 3\text{Aq}$ —555.8 + 54.—A dirty yellow, amorphous mass, obtained by dissolving recently precipitated ferric hydrate in tartaric acid solution, and evaporating below  $59^\circ$  ( $122^\circ$  F.).

A number of double tartrates, containing the group  $(\text{Fe}_2\text{O}_3)$  are also known. Such are: **Ferrico-ammoniac tartrate** = *ferri et ammonii tartras* (U. S.),  $(\text{C}_4\text{H}_4\text{O}_6)_2(\text{Fe}_2\text{O}_3) \cdot (\text{NH}_4)_4 + 4\text{Aq}$ , and **Ferrico-potassic tartrate** = *ferri et potassii tartras*, (U. S.),  $(\text{C}_4\text{H}_4\text{O}_6)_2(\text{Fe}_2\text{O}_3)\text{K}_2$ . They are prepared by dissolving recently precipitated ferric hydrate in hot solutions of the hydro-alkaline tartrate. They only react with ferrocyanids and sulphocyanates after addition of a mineral acid.

**Citrates**.—**Ferric Citrate**—*Ferri citras* (U. S.)— $(\text{Fe}_2)(\text{C}_6\text{H}_5\text{O}_7)_2 + 6\text{Aq}$ —489.8 + 108—is in garnet-colored scales, obtained by dissolving ferric hydrate in solution of citric acid, and evaporating the solution at about  $60^\circ$  ( $140^\circ$  F.). It loses 3Aq at  $120^\circ$  ( $248^\circ$  F.), and the remainder at  $150^\circ$  ( $302^\circ$  F.). If a small quantity of ammonium hydrate be added, before the evaporation, the product consists of the modified citrate = *ferri et ammonii citras* (U. S.), which only reacts with potassium ferrocyanid after addition of HCl.

The various citrates of iron and alkaloids are not definite compounds.

**Ferric Ferrocyanid**—**Prussian blue**— $(\text{Fe}_2)_2(\text{FeC}_6\text{N}_6)_3 + 18\text{Aq}$ —859.3 + 324—is a dark blue precipitate, formed when potassium ferrocyanid is added to a ferric salt. It is insoluble in  $\text{H}_2\text{O}$ , alcohol and dilute acids; soluble in oxalic acid solution (blue ink). Alkalies turn it brown.

**Ferrous Ferricyanid—Turnbull's blue—** $\text{Fe}_3(\text{Fe}_2\text{C}_{12}\text{N}_{12}) + n\text{Aq}$ — $591.5 + n18$ —is a dark blue substance produced by the action of potassium ferricyanid on ferrous salts. Heated in air it is converted into Prussian blue and ferric oxid.

**Analytical Characters.**—**FERROUS**—Are acid; colorless when anhydrous; pale green when hydrated; oxidized by air to basic ferric compounds. (1.) Potash: greenish-white ppt.; insoluble in excess; changing to green or brown in air. (2.) Ammonium hydrate: greenish ppt.; soluble in excess; not formed in presence of ammoniacal salts. (3.) Ammonium sulphhydrate: black ppt.; insoluble in excess; soluble in acids. (4.) Potassium ferrocyanid (in absence of ferric salts): white ppt.; turning blue in air. (5.) Potassium ferricyanid: blue ppt.; soluble in  $\text{KHO}$ ; insoluble in  $\text{HCl}$ .

**FERRIC**—Are acid, and yellow or brown. (1.) Potash, or ammonium hydrate: voluminous, red-brown ppt.; insoluble in excess. (2.) Hydrogen sulphid: in acid solution: milky ppt. of sulphur; ferric reduced to ferrous compound. (3.) Ammonium sulphhydrate: black ppt.; insoluble in excess; soluble in acids. (4.) Potassium ferrocyanid: dark blue ppt.; insoluble in  $\text{HCl}$ ; soluble in  $\text{KHO}$ . (5.) Potassium sulphocyanate: dark red color; prevented by tartaric or citric acid; discharged by mercuric chlorid. (6.) Tannin: blue-black color.

### III. ALUMINIUM GROUP.

**GLUCINIUM—ALUMINIUM—SCANDIUM—GALLIUM—INDIUM.**

This group is placed in the third class by virtue of the existence of the aluminates, and of the relations between the compounds of these elements and some of those of the previous group. They form one series of compounds, corresponding to the ferric, containing the group  $(\text{M}_2)^{\text{vi}}$ , but no compounds corresponding to the ferrous  $\text{M}^{\text{ii}}$  are known. Indeed, certain organic compounds, such as aluminium acetylacetonate,  $\text{Al}(\text{C}_5\text{H}_7\text{O}_2)_3$ , seem to contain single, trivalent atoms of the metal. No acids or salts of the members of the group, other than aluminium, are known: yet their resemblances in other points are such as to forbid their separation.

#### GLUCINIUM.

*Symbol* = **Gl** or **Be** (*Beryllium*)—*Atomic weight* =  $9$ —*Sp. gr.* =  $2.1$ .

A rare element occurring in the emerald and beryl. The metal resembles aluminium and its compounds resemble those of  $\text{Al}$ ,

and, in some respects, those of Mg. Its soluble salts are sweet in taste (*γλυκίς* = sweet).

### ALUMINIUM.

*Symbol* = **Al**—*Atomic weight* = 27—*Molecular weight* = 55 (?)—*Sp. gr.* = 2.56–2.67—*Fuses at about* 700° (1292° F.)—*Name from* alumen=*alum*—*Discovered by* Wöhler, 1827.

**Occurrence.**—Exceedingly abundant in the clays as *silicate*.

**Preparation.**—(1.) By decomposing vapor of aluminium chlorid by Na or K (Wöhler). (2.) Aluminium hydrate, mixed with sodium chlorid and charcoal, is heated in Cl, by which a double chlorid of Na and Al ( $2\text{NaCl}$ ,  $\text{Al}_2\text{Cl}_6$ ) is formed. This is then heated with Na, when Al and NaCl are produced. (The industrial process.)

**Properties.**—*Physical.*—A bluish-white metal; hard; quite malleable, and ductile, when annealed from time to time; slightly magnetic; a good conductor of electricity; non-volatile; very light, and exceedingly sonorous.

*Chemical.*—It is not affected by air or O, except at very high temperatures, and then only superficially. If, however, it contain Si, it burns readily in air, forming aluminium silicate. It does not decompose  $\text{H}_2\text{O}$  at a red heat; but in contact with Cu, Pt, or I, it does so at 100° (212° F.). It combines directly with B, Si, Cl, Br, and I. It is attacked by HCl, gaseous or in solution, with evolution of H, and formation of  $\text{Al}_2\text{Cl}_6$ . It dissolves in alkaline solutions, with formation of **aluminates**, and liberation of H. It alloys with Cu to form a golden yellow metal (**aluminium bronze**).

**Aluminium Oxid**—*Alumina*— $\text{Al}_2\text{O}_3$ —102—occurs in nature, nearly pure, as *corundum*, *emery*, *ruby*, *sapphire* and *topaz*; and is formed artificially, by calcining the hydrate, or ammonia alum, at a red heat.

It is a light, white, odorless, tasteless powder; fuses with difficulty; and, on cooling, solidifies in very hard crystals. Unless it have been heated to bright redness, it combines with  $\text{H}_2\text{O}$ , with elevation of temperature. It is almost insoluble in acids and alkalis.  $\text{H}_2\text{SO}_4$ , diluted with an equal bulk of  $\text{H}_2\text{O}$ , dissolves it slowly as  $(\text{Al}_2)(\text{SO}_4)_3$ . Fused potash and soda combine with it to form aluminates. It is not reduced by charcoal.

**Aluminium Hydrate**—*Aluminium hydroxid*—*Aluminii hydras* (U. S.)— $\text{Al}_2\text{H}_6\text{O}_6$ —156—is formed when a solution of an aluminium salt is decomposed by an alkali, or alkaline carbonate. It constitutes a gelatinous mass, which, when dried, leaves an amorphous, translucent mass; and, when pulverized, a white, tasteless, amorphous powder. When the liquid in which it is formed contains coloring matters, these are carried down with it, and the dried deposits are used as pigments, called **lakes**.

When freshly precipitated, it is insoluble in  $H_2O$ ; soluble in acids, and in solutions of the fixed alkalies. When dried at a temperature above  $50^\circ$  ( $122^\circ F.$ ), or after 24 hours' contact with the mother liquor, its solubility is greatly diminished. With acids it forms salts of aluminium; and with alkalies, aluminates of the alkaline metal. Heated to near redness, it is decomposed into  $Al_2O_3$  and  $H_2O$ . A soluble modification is obtained by dialyzing a solution of  $Al_2H_6O_6$  in  $Al_2Cl_6$ , or by heating a dilute solution of aluminium acetate for 24 hours.

**Aluminates** are for the most part crystalline, soluble compounds, obtained by the action of metallic oxids or hydrates upon alumina. **Potassium aluminate**,  $K_2Al_2O_4 + 3Aq.$  is formed by dissolving recently precipitated aluminium hydrate in potash solution. It forms white crystals; very soluble in  $H_2O$ , insoluble in alcohol; caustic and alkaline. By a large quantity of  $H_2O$  it is decomposed into aluminium hydrate, and a more alkaline salt,  $K_6Al_4O_9$ .

**Sodium Aluminate.**—The aluminate  $Na_2Al_2O_4$  is not known. That having the composition  $Na_6Al_4O_9$  is prepared by heating to redness a mixture of 1 pt. sodium carbonate and 2 pts. of a native ferruginous aluminium hydrate (beauxite). It is insoluble in  $H_2O$ , and is decomposed by carbonic acid, with precipitation of aluminium hydrate.

**Aluminium Chlorid**— $Al_2Cl_6$ —267—is prepared by passing  $Cl$  over a mixture of  $Al_2O_3$  and  $C$ , heated to redness; or by heating clay in a mixture of gaseous  $HCl$  and vapor of  $CS_2$ . \*

It crystallizes in colorless, hexagonal prisms; fusible; volatile; deliquescent; very soluble in  $H_2O$  and in alcohol. From a hot, concentrated solution, it separates in prisms with 12  $Aq.$

The disinfectant called chloralum is a solution of impure  $Al_2Cl_6$ .

**Aluminium Sulphate**—**Aluminii sulphas (U.S.)**— $(Al_2)(SO_4)_3$ —18  $Aq$ —342 + 324—is obtained by dissolving  $Al_2H_6O_6$  in  $H_2SO_4$ ; or (industrially) by heating clay with  $H_2SO_4$ .

It crystallizes, with difficulty, in thin, flexible plates; soluble in  $H_2O$ ; very sparingly soluble in alcohol. Heated, it fuses in its  $Aq.$  which it gradually loses up to 200 ( $392^\circ F.$ ), when a white, amorphous powder,  $(Al_2)(SO_4)_3$ , remains; this is decomposed at a red heat, leaving a residue of pure alumina.

**Alums**—are double sulphates of the alkaline metals, and the higher sulphates of this, or the preceding group. When crystallized, they have the general formula:  $(M_2)^{VI}(SO_4)_3.R_2SO_4 + 24 Aq.$  in which  $(M)$  may be  $(Fe_2)$ ,  $(Mn_2)$ ,  $(Cr_2)$ ,  $(Al_2)$ , or  $(Ga_2)$ ; and  $R_2$  may be  $K_2$ ,  $Na_2$ ,  $Rb_2$ ,  $Cs_2$ ,  $Tl_2$ , or  $(NH_4)_2$ . They are isomorphous with each other.

**Alumen (U. S.)**— $Al_2(SO_4)_3.K_2SO_4 + 24 Aq$ —516 + 432—is manufactured from "alum shale," and is formed when solutions of the sulphates of  $Al$  and  $K$  are mixed in suitable proportion.

It crystallizes in large, transparent, regular octahedra: has a sweetish, astringent taste, and is readily soluble in  $H_2O$ . Heated, it fuses in its Aq at  $92^\circ$  ( $197.6^\circ F.$ ); and gradually loses 45.5 per cent. of its weight of  $H_2O$ , as the temperature rises to near redness. The product, known as burnt alum = *alumen exsiccatum* (U. S.), is  $(Al)_2(SO_4)_3$ ,  $K_2SO_4$ , and is slowly, but completely soluble in 20-30 pts.  $H_2O$ . At a bright red heat,  $SO_2$  and O are given off, and  $Al_2O_3$  and potassium sulphate remain: at a higher temperature, potassium aluminate is formed. Its solutions are acid in reaction; dissolve Zn and Fe with evolution of H; and deposit  $Al_2H_2O_6$  when treated with ammonium hydrate.

**Alumen (Br.)**— $Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 + 24 Aq - 474 + 432$ —is the compound now usually met with as alum, both in this country and in England. It differs from potash alum in being more soluble in  $H_2O$ , between  $20-30^\circ$  ( $68-86^\circ F.$ ), and less soluble at other temperatures: and in the action of heat upon it. At  $92^\circ$  ( $197.6^\circ F.$ ) it fuses in its Aq: at  $205^\circ$  ( $401^\circ F.$ ) it loses its ammonium-sulphate, leaving a white, hygroscopic substance, very slowly and incompletely soluble in  $H_2O$ . More strongly heated, it leaves alumina.

**Silicates**—are very abundant in the different varieties of *clay*, *feldspar*, *albite*, *labradorite*, *mica*, etc. The clays are hydrated aluminium silicates, more or less contaminated with alkaline and earthy salts and iron, to which last certain clays owe their color. The purest is *kaolin*, or porcelain clay, a white or grayish powder. They are largely used in the manufacture of the different varieties of bricks, terra cotta, pottery, and porcelain. *Porcelain* is made from the purer clays, mixed with sand and feldspar: the former to prevent shrinkage, the latter to bring the mixture into partial fusion, and to render the product translucent. The fashioned articles are subjected to a first baking. The porous, baked clay is then coated with a *glaze*, usually composed of oxid of lead, sand, and salt. During a second baking, the glaze fuses, and coats the article with a hard, impermeable layer. The coarser articles of pottery are glazed by throwing sodium chlorid into the fire: the salt is volatilized, and, on contact with the hot aluminium silicate, deposits a coating of the fusible sodium silicate, which hardens on cooling.

**Analytical Characters.**—(1.) Potash, or soda; white ppt.: soluble in excess. (2.) Ammonium hydrate; white ppt.: almost insoluble in excess, especially in presence of ammoniacal salts. (3.) Sodium phosphate; white ppt.: readily soluble in  $KHO$  and  $NaHO$ , but not in  $NH_4HO$ : soluble in mineral acids, but not in acetic acid. (4.) Blowpipe—on charcoal does not fuse, and moistened with cobalt nitrate solution turns dark sky-blue.

## SCANDIUM.

*Symbol = Sc—Atomic weight = 44.9—Discovered by Nilson (1879)*  
*—Name from Scandia.*

Occurs in minute traces in gadolinite and euxenite. It forms an oxid,  $\text{Sc}_2\text{O}_3$ ; a light, white, infusible powder; sp. gr. 3.8; resembling alumina.

## GALLIUM.

*Symbol = Ga—Atomic weight = 68.8—Sp. gr. = 5.9—Fuses at 36° (86° F.)—Name from Gallia—Discovered by Lecoq de Boisbaudran (1876).*

Occurs in very small quantity in certain zinc blendes. It is a hard, white metal; soluble in hot  $\text{HNO}_3$ , in  $\text{HCl}$ , and in  $\text{KHO}$  solution. In chemical characters it closely resembles  $\text{Al}$ ; forms an oxid,  $\text{Ga}_2\text{O}_3$ , and a series of alums.

The discovery of  $\text{Sc}$  and  $\text{Ga}$  affords most flattering verifications of predictions based upon purely theoretical considerations.

It has been observed that there exist numerical relations between the atomic weights of the elements, which, in groups of allied elements, differ from each other by (approximately) some multiple of eight. Upon this variation Mendelejeff has based what is known as the **Periodic Law**, to the effect that: "**The properties of elements, the constitution of their compounds, and the properties of the latter, are periodic functions of the atomic weights of the elements.**"

In accordance with this law the elements may be thus arranged :

Series.	Group I.	Group II.	Group III.	Group IV.	Group V.	Group VI.	Group VII.	Group VIII.
	$\text{R}_2\text{O}$ $\text{H}=1$	$\text{RO}$	$\text{R}_2\text{O}_3$	$\text{RH}_4$ $\text{RO}_2$	$\text{RH}_3$ $\text{R}_2\text{O}_5$	$\text{RH}_2$ $\text{RO}_3$	$\text{RH}$ $\text{R}_2\text{O}_7$	$(\text{R}_2\text{H})$ $(\text{RO}_4)$
1.....	$\text{Li}=7$	$\text{Be}=9$	$\text{B}=11$	$\text{C}=12$	$\text{N}=14$	$\text{O}=16$	$\text{F}=19$	
2.....	$\text{Na}=23$	$\text{Mg}=24$	$\text{Al}=27$	$\text{Si}=28$	$\text{P}=31$	$\text{S}=32$	$\text{Cl}=35$	$\text{Cu}=63$
3.....	$\text{K}=39$	$\text{Ca}=40$	$\text{Sc}=44$	$\text{Ti}=48$	$\text{V}=51$	$\text{Cr}=52$	$\text{Mn}=55$	$\text{Fe}=56$
4.....								$\text{Co}=59$
5.....								$\text{Ni}=59$
6.....	$(\text{Cu}=63)$	$\text{Zn}=65$	$\text{Ga}=69$	$\text{Ge}=72$	$\text{As}=75$	$\text{Se}=78$	$\text{Br}=80$	$\text{Ru}=104$
7.....								$\text{Rh}=104$
8.....	$\text{Rb}=85$	$\text{Sr}=87$	$\text{Yt}=88$	$\text{Zr}=90$	$\text{Nb}=94$	$\text{Mo}=96$	$?=100$	$\text{Pd}=106$

12.....			$\text{E}=166$					$\text{Os}=195$
								$\text{Ir}=193$
			$\text{Yb}=173$		$\text{Ta}=182$	$\text{W}=184$	$?=190$	$\text{Pt}=195$
								$\text{Au}=197$
	$(\text{Au}=196)$	$\text{Hg}=200$	$\text{Tl}=204$	$\text{Pb}=207$	$\text{Bi}=208$			
				$\text{Th}=231$		$\text{U}=238$		

The atomic weights and chemical characters, which were announced by Mendelejeff in 1870 as those of the undiscovered elements which would occupy the positions 4 and 5 in group III. have been since found to be those of Se and Ga. Still later, the vacant positions 10, III., 5, IV., 8, VI., and 8, V., have been filled by the discovery of Yb, Ge, Sm, and Da.

#### INDIUM.

*Symbol = In—Atomic weight = 113.4—Sp. gr. = 7.42—Fuses at 176 (348.8 F.)—Discovered by Reich and Richter in 1863.*

A soft, silver-white, ductile metal, which occurs in small quantity in certain zinc blendes. It is characterized spectroscopically by two principal lines— $\lambda = 4511$  and  $4101$ .

#### IV. URANIUM GROUP.

##### URANIUM.

*Symbol = Ur—Atomic weight = 238.5—Sp. gr. = 18.4—Discovered by Klaproth (1789).*

This element is usually classed with Fe and Cr, or with Ni and Co. It does not, however, form compounds resembling the ferric; it forms a series of well-defined *uranates*, and a series of compounds of the radical *uranyl* ( $UO_2$ ). Standard solutions of its acetate or nitrate are used for the quantitative determination of  $H_3PO_4$ .

#### V. LEAD GROUP.

##### LEAD.

*Symbol = Pb (PLUMBUM)—Atomic weight = 206.9—Molecular weight = 413.8 (?)—Sp. gr. = 11.445—Fuses at 325° (617° F.)—Name from lød = heavy (Saxon).*

Lead is usually classed with Cd, Bi, or Cu and Hg. It differs, however, from Bi in being bivalent or quadrivalent, but not trivalent, and in forming no compounds, resembling those of bismuthyl ( $BiO$ ); from Cd, in the nature of its O compounds; and from Cu and Hg in forming no compounds similar to the mercurous and cuprous salts. Indeed, the nature of the Pb compounds is such that the element is best classed in a group by itself, which finds a place in this class by virtue of the existence of potassium plumbate.

**Occurrence.**—Its most abundant ore is galena,  $\text{PbS}$ . It also occurs in white lead ore,  $\text{PbCO}_3$ , in anglesite,  $\text{PbSO}_4$ , and in horn lead,  $\text{PbCl}_2$ .

**Preparation.**—Galena is first roasted with a little lime. The mixture of  $\text{PbO}$ ,  $\text{PbS}$ , and  $\text{PbSO}_4$ , so obtained, is strongly heated in a reverberatory furnace, when  $\text{SO}_2$  is driven off. The impure *work lead*, so formed, is purified by fusion in air, and removal of the film of oxids of Sn and Sb. If the ore be rich in Ag, that metal is extracted, by taking advantage of the greater fusibility of an alloy of Pb and Ag, than of Pb alone; and subsequent oxidation of the remaining Pb.

**Properties.**—*Physical.*—It is a bluish-white metal; brilliant upon freshly cut surfaces; very soft and pliable; not very malleable or ductile; crystallizes in octahedra; a poor conductor of electricity; a better conductor of heat. When expanded by heat, it does not, on cooling, return to its original volume.

*Chemical.*—When exposed to air it is oxidized, more readily and completely at high temperatures. The action of  $\text{H}_2\text{O}$  on Pb varies with the conditions. Pure unærated  $\text{H}_2\text{O}$  has no action upon it. By the combined action of air and moisture Pb is oxidized, and the oxid dissolved in the  $\text{H}_2\text{O}$ , leaving a metallic surface for the continuance of the action. The solvent action of  $\text{H}_2\text{O}$  upon Pb is increased, owing to the formation of basic salts, by the presence of nitrogenized organic substances, nitrates, nitrites, and chlorids. On the other hand, carbonates, sulphates, and phosphates, by their tendency to form insoluble coatings, diminish the corroding action of  $\text{H}_2\text{O}$ . Carbonic acid in small quantity, especially in presence of carbonates, tends to preserve Pb from solution, while  $\text{H}_2\text{O}$  highly charged with it (soda water) dissolves the metal readily. Lead is dissolved, as a nitrate, by  $\text{HNO}_3$ .  $\text{H}_2\text{SO}_4$  when cold and moderately concentrated, does not affect it; but, when heated, dissolves it the more readily as the acid is more concentrated. It is attacked by  $\text{HCl}$  of sp. gr. 1.12, especially if heated. Acetic acid dissolves it as acetate, or, in the presence of  $\text{CO}_2$ , converts it into white lead.

**Oxids.**—**Lead Monoxid**—*Protoxid*—**Massicot**—**Litharge**—**Plumbi oxidum** (U. S.; Br.)— $\text{PbO}$ —222.9—is prepared by heating Pb, or its carbonate, or nitrate, in air. If the product have been fused, it is litharge; if not, massicot. It forms copper-colored, mica-like plates, or a yellow powder; or crystallizes, from its solution in soda or potash, in white, rhombic dodecahedra, or in rose-colored cubes. It fuses near a red heat, and volatilizes at a white heat; sp. gr. 9.277–9.5. It is sparingly soluble in  $\text{H}_2\text{O}$ , forming an alkaline solution.

Heated in air to 300 (572 F.) it is oxidized to minium. It is

readily reduced by H or C. With Cl it forms  $\text{PbCl}_2$  and O. It is a strong base; decomposes alkaline salts, with liberation of the alkali. It dissolves in  $\text{HNO}_3$ , and in hot acetic acid, as nitrate or acetate. When ground up with oils it saponifies the glycerin ethers, the Pb combining with the fatty acids to form Pb soaps, one of which, lead oleate, is the *emplastrum plumbi*, U. S.; Br. It also combines with the alkalies and earths to form *plumbites*. Calcium plumbite,  $\text{CaPb}_2\text{O}_3$ , is a crystalline salt, formed by heating PbO with milk of lime, and used in solution as a hair-dye.

**Plumboso-plumbic Oxid**—*Red oxid*—**Minium**—**Red lead**— $\text{Pb}_3\text{O}_4$ —684.7—is prepared by heating massicot to 300 (572° F.) in air. It ordinarily has the composition  $\text{Pb}_3\text{O}_4$ , and has been considered as composed of  $\text{PbO}_2$ , 2PbO; or as a basic lead salt of plumbic acid,  $\text{PbO}_3\text{Pb}$ , PbO. An orange-colored variety is formed when lead carbonate is heated to 300° (572° F.).

It is a bright red powder, sp. gr. 8.62. It is converted into PbO when strongly heated, or by the action of reducing agents.  $\text{HNO}_3$  changes its color to brown, dissolving PbO and leaving  $\text{PbO}_2$ . It is decomposed by HCl, with formation of  $\text{PbCl}_2$ ,  $\text{H}_2\text{O}$  and Cl.

**Lead Dioxid**—*Peroxid*, or *puce oxid*, or *brown oxid*, or *binoxid of lead*—**Plumbic anhydrid**— $\text{PbO}_2$ —238.9—is prepared, either by dissolving the PbO out of red lead by dilute  $\text{HNO}_3$ , or by passing a current of Cl through  $\text{H}_2\text{O}$ , holding lead carbonate in suspension.

It is a dark, reddish-brown, amorphous powder; sp. gr. 8.903–9.190; insoluble in  $\text{H}_2\text{O}$ . Heated, it loses half its O, and is converted into PbO. It is a valuable oxidant. It absorbs  $\text{SO}_2$  to form  $\text{PbSO}_4$ . It combines with alkalies to form *plumbates*,  $\text{M}_2\text{PbO}_3$ .

**Plumbic Acid**— $\text{PbO}_3\text{H}_2$ —256.9—forms crystalline plates, at the + electrode, when alkaline solutions of the Pb salts are decomposed by a weak current.

**Lead Sulphid**—**Galena**— $\text{PbS}$ —338.9—exists in nature. It is also formed by direct union of Pb and S; by heating PbO with S, or vapor of  $\text{CS}_2$ ; or by decomposing a solution of a Pb salt by  $\text{H}_2\text{S}$  or an alkaline sulphid.

The native sulphid is a bluish-gray, and has a metallic lustre; sp. gr. 7.58; that formed by precipitation is a black powder; sp. gr. 6.924. It fuses at a red heat and is partly sublimed, partly converted into a subsulphate. Heated in air it is converted into  $\text{PbSO}_4$ , PbO and  $\text{SO}_2$ . Heated in H it is reduced. Hot  $\text{HNO}_3$  oxidizes it to  $\text{PbSO}_4$ . Hot HCl converts it into  $\text{PbCl}_2$ . Boiling  $\text{H}_2\text{SO}_4$  converts it into  $\text{PbSO}_4$  and  $\text{SO}_2$ .

**Lead Chlorid**— $\text{PbCl}_2$ —277.9—is formed by the action of Cl upon Pb at a red heat; by the action of boiling HCl upon Pb; and by double decomposition between a lead-salt and a chlorid.

It crystallizes in plates, or hexagonal needles; sparingly soluble in cold  $\text{H}_2\text{O}$ , less soluble in  $\text{H}_2\text{O}$  containing  $\text{HCl}$ ; more soluble in hot  $\text{H}_2\text{O}$ , and in concentrated  $\text{HCl}$ .

Several oxychlorids are known. **Cassel, Paris, Verona, or Turner's yellow** is  $\text{PbCl}_2$ ,  $7\text{PbO}$ .

**Lead Iodid—Plumbi iodidum (U. S.; Br.)—** $\text{PbI}_2$ —460.9—is deposited, as a bright yellow powder, when a solution of potassium iodid is added to a solution of a Pb salt. Fused in air, it is converted into an oxyiodid. Light and moisture decompose it, with liberation of I. It is almost insoluble in  $\text{H}_2\text{O}$ , soluble in solutions of ammonium chlorid, sodium hyposulphite, alkaline iodids, and potash.

**Nitrates. — Lead Nitrate — Plumbi nitras — (U. S.; Br.)—** $\text{Pb}(\text{NO}_3)_2$ —330.9—is formed by solution of Pb, or of its oxids, in excess of  $\text{HNO}_3$ . It forms anhydrous crystals; soluble in  $\text{H}_2\text{O}$ . Heated, it is decomposed into  $\text{PbO}$ , O and  $\text{NO}_2$ .

Besides the neutral nitrate, basic lead nitrates are known, which seem to indicate the existence of nitrogen acids similar to those of phosphorus;  $\text{Pb}_3(\text{NO}_4)_2$ —*orthonitrate*; and  $\text{Pb}_2\text{N}_2\text{O}_7$ —*pyronitrate*.

**Lead Sulphate—** $\text{PbSO}_4$ —302.9—is formed by the action of hot, concentrated  $\text{H}_2\text{SO}_4$  on Pb; or by double decomposition between a sulphate and a Pb salt in solution. It is a white powder, almost insoluble in  $\text{H}_2\text{O}$ , soluble in concentrated  $\text{H}_2\text{SO}_4$ , from which it is deposited by dilution.

**Lead Chromate—Chrome yellow—** $\text{PbCrO}_4$ —323.3—is formed by decomposing  $\text{Pb}(\text{NO}_3)_2$  with potassium chromate. It is a yellow, amorphous powder, insoluble in  $\text{H}_2\text{O}$ , soluble in alkalies.

**Acetates.—Neutral Lead Acetate—Salt of Saturn—Sugar of Lead—Plumbi acetas (U.S.; Br.)—** $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 + 3\text{Aq}$ —324.9 + 54—is formed by dissolving  $\text{PbO}$  in acetic acid; or by exposing Pb in contact with acetic acid to air.

It crystallizes in large, oblique rhombic prisms, sweetish, with a metallic after-taste; soluble in  $\text{H}_2\text{O}$  and alcohol; its solutions being acid. In air it effloresces, and is superficially converted into carbonate. It fuses at  $75.5$  ( $167.9^\circ\text{F.}$ ); loses  $\text{Aq.}$  and a part of its acid at  $100$  ( $212^\circ\text{F.}$ ), forming the sesquibasic acetate; at  $280$  ( $536^\circ\text{F.}$ ) it enters into true fusion, and, at a slightly higher temperature, is decomposed into  $\text{CO}_2$ ; Pb, and acetone. Its aqueous solution dissolves  $\text{PbO}$ , with formation of basic acetates.

**Sexbasic Lead Acetate—** $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)\text{OH}$ ,  $2\text{PbO}$ —728.7—is the main constituent of **Goulard's extract** = *Liq. plumbi subacetatis* (U. S.; Br.), and is formed by boiling a solution of the neutral acetate with  $\text{PbO}$  in fine powder. The solution becomes milky on addition of ordinary  $\text{H}_2\text{O}$ , from formation of the sulphate and carbonate.

**Lead Carbonate**— $\text{PbCO}_3$ —266.9—occurs in nature as cerusite; and is formed, as a white, insoluble powder, when a solution of a Pb compound is decomposed by an alkaline carbonate, or by passing  $\text{CO}_2$  through a solution containing Pb.

The **plumbi carbonas** (**U. S.** ; **Br.**), or **white lead** or **ceruse**, is a basic carbonate ( $\text{PbCO}_3$ )<sub>2</sub>.  $\text{PbH}_2\text{O}_2$ —774.7—mixed with varying proportions of other basic carbonates. It is usually prepared by the action of  $\text{CO}_2$  on a solution of the subacetate, prepared by the action of acetic acid on Pb and PbO. It is a heavy, white powder: insoluble in  $\text{H}_2\text{O}$ , except in the presence of  $\text{CO}_2$ ; soluble in acids with effervescence; and decomposed by heat into  $\text{CO}_2$  and PbO.

**Analytical Characters.**—(1.) Hydrogen sulphid, in acid solution: a black ppt.; insoluble in alkaline sulphids, and in cold, dilute acids. (2.) Ammonium sulphhydrate: black ppt.; insoluble in excess. (3.) Hydrochloric acid: white ppt.; in not too dilute solution; soluble in boiling  $\text{H}_2\text{O}$ . (4.) Ammonium hydrate: white ppt.; insoluble in excess. (5.) Potash: white ppt.; soluble in excess, especially when heated. (6.) Sulphuric acid: white ppt.; insoluble in weak acids, soluble in solution of ammonium tartrate. (7.) Potassium iodid: yellow ppt.; sparingly soluble in boiling  $\text{H}_2\text{O}$ ; soluble in large excess. (8.) Potassium chromate: yellow ppt.; soluble in KHO solution. (9.) Iron or zinc separate the element from solution of its salts.

**Action on the Economy.**—All the soluble compounds of Pb, and those which, although not soluble, are readily convertible into soluble compounds by  $\text{H}_2\text{O}$ , air, or the digestive fluids, are actively poisonous. Some are also injurious by their local action upon tissues with which they come in contact: such are the acetate, and, in less degree, the nitrate.

The chronic form of lead intoxication, **painter's colic**, etc., is purely poisonous, and is produced by the continued absorption of minute quantities of Pb, either by the skin, lungs, or stomach. The **acute** form presents symptoms referable to the local, as well as to the poisonous, action of the Pb salt, and is usually caused by the ingestion of a single dose of the acetate or carbonate.

**Metallic Pb**, although probably not poisonous of itself, causes chronic lead-poisoning by the readiness with which it is convertible into compounds capable of absorption. The principal sources of poisoning by metallic Pb are: the contamination of drinking water which has been in contact with the metal (see p. 72); the use of articles of food, or of chewing tobacco, which has been packed in tin-foil, containing an excess of Pb; the drinking of beer or other beverages which have been in contact with pewter; or the handling of the metal and its alloys.

Almost all the compounds of Pb may produce painter's colic. The carbonate, in painters, artists, manufacturers of white lead, and in persons sleeping in newly painted rooms; the oxids, in the manufactures of glass, pottery, sealing-wax, and litharge, and by the use of lead-glazed pottery; by other compounds, by the inhalation of the dust of cloth factories, and by the use of lead hair-dyes.

Acute lead-poisoning is of by no means as common occurrence as the chronic form, and usually terminates in recovery. It is caused by the ingestion of a single large dose of the acetate, subacetate, carbonate, or of red lead. In such cases the administration of magnesium sulphate is indicated; it enters into double decomposition with the Pb salt to form the insoluble  $PbSO_4$ .

Lead, once absorbed, is eliminated very slowly, it becoming fixed by combination with the albuminoids, a form of combination which is rendered soluble by potassium iodid. The channels of elimination are by the perspiration, urine and bile.

In the analysis for mineral poisons (see p. 136), the major part of the Pb is precipitated as  $PbS$  in the treatment by  $H_2S$ . The  $PbS$  remains upon the filter after extraction with ammonium sulphhydrate. It is treated with warm  $HCl$ , which decolorizes it by transforming the sulphid into chlorid. The  $PbCl_2$  thus formed is dissolved in hot  $H_2O$ , from which it crystallizes on cooling. The solution still contains  $PbCl_2$  in sufficient quantity to respond to the tests for the metal.

Although Pb is not a normal constituent of the body, the every-day methods by which it may be introduced into the economy, and the slowness of its elimination, are such as to render the greatest caution necessary in drawing conclusions from the detection of Pb in the body after death.

## VI. BISMUTH GROUP.

### BISMUTH.

*Symbol* = Bi—*Atomic weight* = 207.5—*Molecular weight* = 420 (?)—*Sp. gr.* = 9.677–9.935—*Fuses at* 268° (514°.4 F.).

This element is usually classed with Sb; by some writers among the metals, by others in the phosphorous group. We are led to class Bi in our third class, and in a group alone, because: (1) while the so-called salts of Sb are not salts of the element, but of the radical  $(SbO)$ , *antimonyl*, Bi enters into saline combination, not only in the radical *bismuthyl*  $(BiO)$ , but also as an element; (2) while the compounds of the elements of the N group in which those elements are quinquivalent are, as a rule, more stable than those in which they are trivalent, Bi is trivalent in all its known

compounds except one, which is very unstable, in which it is quinquivalent; (3) the hydrates of the N group are strongly acid, and their corresponding salts are stable and well defined; but those hydrates of Bi which are acid are but feebly so, and the bismuthates are unstable; (4) no compound of Bi and H is known.

**Occurrence.**—Occurs principally free, also as  $\text{Bi}_2\text{O}_3$  and  $\text{Bi}_2\text{S}_3$ .

**Properties.**—Crystallizes in brilliant, metallic rhombohedra: hard and brittle.

It is only superficially oxidized in cold air. Heated to redness in air, it becomes coated with a yellow film of oxid. In  $\text{H}_2\text{O}$ , containing  $\text{CO}_2$ , it forms a crystalline subcarbonate. It combines directly with Cl, Br, and I. It dissolves in hot  $\text{H}_2\text{SO}_4$  as sulphate, and in  $\text{HNO}_3$  as nitrate.

It is usually contaminated with As, from which it is best purified by heating to redness a mixture of powdered bismuth, potassium carbonate, soap and charcoal, under a layer of charcoal. After an hour the mass is cooled: the button is separated and fused until its surface begins to be coated with a yellowish-brown oxid.

**Oxids.**—Four oxids are known:  $\text{Bi}_2\text{O}_2$ ;  $\text{Bi}_2\text{O}_3$ ;  $\text{Bi}_2\text{O}_4$ ; and  $\text{Bi}_2\text{O}_5$ .

**Bismuth Trioxid**—*Bismuthous oxid*—*Protoxid*— $\text{Bi}_2\text{O}_3$ —468—is formed by heating Bi, or its nitrate, carbonate, or hydrate. It is a pale yellow, insoluble powder; sp. gr. 8.2; fuses at a red heat; soluble in  $\text{HCl}$ ,  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  and in fused potash.

**Hydrates.**—Bismuth forms at least four hydrates.

**Bismuthous Hydrate**— $\text{BiH}_3\text{O}_3$ —261—is formed, as a white precipitate, when potash or ammonium hydrate is added to a cold solution of a Bi salt. When dried, it loses  $\text{H}_2\text{O}$ , and is converted into **bismuthyl hydrate**  $(\text{BiO})\text{HO}$ .

**Bismuthic Acid**— $(\text{BiO}_2)\text{HO}$ —259—is deposited, as a red powder, when Cl is passed through a boiling solution of potash, holding bismuthous hydrate in suspension. When heated it is converted into the **pentoxid**,  $\text{Bi}_2\text{O}_5$ .

**Pyrobismuthic Acid**— $\text{H}_4\text{Bi}_2\text{O}_7$ —536—is a dark brown powder, precipitated from solution of bismuth nitrate by potassium cyanid.

**Bismuth Trichlorid**—*Bismuthous chlorid*— $\text{BiCl}_3$ —316.5—is formed by heating Bi in Cl; by distilling a mixture of Bi and mercuric chlorid; or by distilling a solution of Bi in aqua regia. It is a fusible, volatile, deliquescent solid; soluble in dilute  $\text{HCl}$ . On contact with  $\text{H}_2\text{O}$  it is decomposed with formation of **bismuthyl chlorid**  $(\text{BiO})\text{Cl}$ , or **pearl white**.

**Bismuth Nitrate**— $\text{Bi}(\text{NO}_3)_3 + 5 \text{ Aq}$ —396+90—obtained by dissolving Bi in  $\text{HNO}_3$ . It crystallizes in large, colorless prisms; at 150 (302° F.), or by contact with  $\text{H}_2\text{O}$ , it is converted into bismuthyl nitrate; at 260° (500° F.) into  $\text{Bi}_2\text{O}_3$ .

**Bismuthyl Nitrate**—*Trisnitrate or subnitrate of bismuth—Flake white*—Bismuthi subnitrates (U. S.; Br.)— $(\text{BiO})\text{NO}_3 \cdot \text{H}_2\text{O}$ —306—is formed by decomposing a solution of  $\text{Bi}(\text{NO}_3)_3$  with a large quantity of  $\text{H}_2\text{O}$ . It is a white, heavy, faintly acid powder; soluble to a slight extent in  $\text{H}_2\text{O}$  when freshly precipitated, the solution depositing it again on standing. It is decomposed by pure  $\text{H}_2\text{O}$ , but not by  $\text{H}_2\text{O}$  containing  $\frac{1}{500}$  ammonium nitrate. It usually contains 1 Aq, which it loses at 100 (212° F.).

Bismuth subnitrate, as well as the subcarbonate, is liable to contamination with arsenic, which accompanies bismuth in its ores. The method for separating this dangerous impurity, directed by the British Pharmacopœia, is more perfect than that usually followed in this country. The metal is first purified by fusion with potassium nitrate, which dissolves any arsenic present in the form of sodium arsenite, and the purified metal is then converted into nitrate by solution in  $\text{HNO}_3$ , and this in turn into subnitrate by decomposition with a large volume of  $\text{H}_2\text{O}$ .

The maximum amount of arsenic which has been found in commercial bismuth subnitrate is one-tenth of one per cent.

To detect the presence of arsenic, the subnitrate (or subcarbonate) is boiled for half an hour with an equal weight of *pure* sodium carbonate, dissolved in ten times its weight of  $\text{H}_2\text{O}$ . The solution is filtered; the filtrate evaporated to dryness; the residue strongly heated; and, after cooling, cautiously decomposed with strong  $\text{H}_2\text{SO}_4$ . The mass is then gradually heated, during stirring, until dense white fumes are given off. The cooled residue is finally treated with water and the liquid introduced into a Marsh apparatus. (See page 133.)

**Bismuthyl Subcarbonate**—Bismuthi subcarbonas (U. S.)—Bismuthi carbonas (Br.)— $(\text{BiO})_2\text{CO}_3 \cdot \text{H}_2\text{O}$ —530—is a white or yellowish, amorphous powder, formed when a solution of an alkaline carbonate is added to a solution of  $\text{Bi}(\text{NO}_3)_3$ . It is odorless and tasteless, and insoluble in  $\text{H}_2\text{O}$  and in alcohol.

When heated to 100 (212° F.), it loses  $\text{H}_2\text{O}$ , and is converted into  $(\text{BiO})_2\text{CO}_3$ . At a higher temperature it is further decomposed into  $\text{Bi}_2\text{O}_3$  and  $\text{CO}_2$ .

**Analytical Characters.**—(1.) Water: white ppt., even in presence of tartaric acid, but not of  $\text{HNO}_3$ ,  $\text{HCl}$ , or  $\text{H}_2\text{SO}_4$ . (2.) Hydrogen sulphid: black ppt.; insoluble in dilute acids and in alkaline sulphids. (3.) Ammonium sulphhydrate: black ppt.; insoluble in excess. (4.) Potash, soda, or ammonia: white ppt., in-

soluble in excess, and in tartaric acid; turns yellow when the liquid is boiled. (5.) Potassium ferrocyanid: yellowish ppt.; insoluble in HCl. (6.) Potassium ferriecyanid: yellowish ppt.; soluble in HCl. (7.) Infusion of galls: orange ppt. (8.) Potassium iodid: brown ppt.; soluble in excess. (9.) Reacts with Reinsch's test (*q. v.*), but gives no sublimate in the glass tube.

**Action on the Economy.**—Although the medicinal compounds of bismuth are probably poisonous, if taken in sufficient quantity, the ill effects ascribed to them are in most, if not all cases, referable to contamination with arsenic. Symptoms of arsenical poisoning have been frequently observed when the subnitrate has been taken internally, and also when it has been used as a cosmetic.

When preparations of bismuth are administered, the alvine discharges contain bismuth sulphid, as a dark brown powder.

## VII. TIN GROUP.

### TITANIUM. ZIRCONIUM. TIN.

Ti and Sn are bivalent in one series of compounds,  $\text{SnCl}_2$ , and quadrivalent in another,  $\text{SnCl}_4$ . Zr, so far as known, is always quadrivalent. Each of these elements forms an acid (or salts corresponding to one) of the composition  $\text{H}_2\text{MO}_2$ , and a series of oxysalts of the composition  $\text{M}^{\text{iv}}(\text{NO}_3)_4$ .

### TITANIUM.

*Symbol = Ti—Atomic weight = 48—Sp. gr. = 5.3.*

Occurs in clays and iron ores, and as  $\text{TiO}_2$  in several minerals. **Titanic anhydrid**,  $\text{TiO}_2$ , is a white, insoluble, infusible powder, used in the manufacture of artificial teeth; dissolves in fused  $\text{KHO}$ , as potassium titanate. Titanium combines readily with N, which it absorbs from air when heated. When  $\text{NH}_3$  is passed over red-hot  $\text{TiO}_2$ , it is decomposed with formation of the violet nitrid,  $\text{TiN}_2$ . Another compound of Ti and N forms hard, copper-colored, cubical crystals.

### ZIRCONIUM.

*Symbol = Zr—Atomic weight = 89.6—Sp. gr. = 4.15.*

Occurs in zircon and hyacinth. Its oxid, **zirconia**,  $\text{ZrO}_2$ , is a white powder, insoluble in  $\text{KHO}$ . Being infusible, and not altered by exposure to air, it is used in pencils to replace lime in the calcium light.

## TIN.

*Symbol = Sn (STANNUM)—Atomic weight = 117.7—Molecular weight = 235.4 (?)—Sp. gr. = 7.285–7.293—Fuses at 228° (442° F.).*

**Occurrence.**—As **tinstone** ( $\text{SnO}_2$ ) or **cassiterite**, and in **stream tin**.

**Preparation.**—The commercial metal is prepared by roasting the ore, extracting with  $\text{H}_2\text{O}$ , reducing the residue by heating with charcoal, and refining.

Pure tin is obtained by dissolving the metal in  $\text{HCl}$ ; filtering; evaporating; dissolving the residue in  $\text{H}_2\text{O}$ ; decomposing with ammonium carbonate; and reducing the oxid with charcoal.

**Properties.**—A soft, malleable, bluish-white metal; but slightly tenacious; emits a peculiar sound, the **tin-cry**, when bent. A good conductor of heat and electricity. Air affects it but little, except when it is heated; more rapidly if Sn be alloyed with Pb. It oxidizes slowly in  $\text{H}_2\text{O}$ , more rapidly in the presence of sodium chlorid. Its presence with Pb accelerates the action of  $\text{H}_2\text{O}$  upon the latter. It dissolves in  $\text{HCl}$  as  $\text{SnCl}_2$ . In presence of a small quantity of  $\text{H}_2\text{O}$ ,  $\text{HNO}_3$  converts it into metastannic acid. Alkaline solutions dissolve it as metastannates. It combines directly with Cl, Br, I, S, P, and As.

**Tin plates** are thin sheets of Fe, coated with Sn. **Tin foil** consists of thin laminae of Sn, frequently alloyed with Pb. Copper and iron vessels are **tinned** after brightening, by contact with molten Sn. Pewter, bronze, bell metal, gun metal, britannia metal, speculum metal, type metal, solder, and fusible metal contain Sn.

**Oxids.**—**Stannous Oxid**—*Protoxid*— $\text{SnO}$ —133.7—obtained by heating the hydrate or oxalate without contact of air. It is a white, amorphous powder, soluble in acids, and in hot concentrated solution of potash. It absorbs O readily.

**Stannic Oxid.**—*Binoxid of tin*— $\text{SnO}_2$ —149.7—occurs native as *tinstone* or *cassiterite*, and is formed when Sn or  $\text{SnO}$  is heated in air. It is used as a polishing material, under the name of **putty powder**.

**Hydrates.**—**Stannous Hydrate**— $\text{SnH}_2\text{O}_2$ —151.7—is a white precipitate, formed by alkaline hydrates and carbonates in solutions of  $\text{SnCl}_2$ .

**Stannic Acid.**— $\text{H}_2\text{SnO}_3$ —167.7—is formed by the action of alkaline hydrates on solutions of  $\text{SnCl}_4$ . It dissolves in solutions of the alkaline hydrates, forming **stannates**.

**Metastannic Acid.**— $\text{H}_2\text{Sn}_3\text{O}_{11}$ —766.5—is a white, insoluble powder, formed by acting on Sn with  $\text{HNO}_3$ .

**Chlorids.**—**Stannous Chlorid**—*Protochlorid*—**Tin crystals**— $\text{SnCl}_2 + 2 \text{Aq}$ —188.7 + 36—is obtained by dissolving Sn in  $\text{HCl}$ . It

crystallizes in colorless prisms; soluble in a small quantity of  $H_2O$ ; decomposed by a large quantity, unless in the presence of free  $HCl$ , with formation of an oxychlorid. Loses its  $Aq$  at  $100^\circ$  ( $212^\circ F.$ ). In air it is transformed into stannic chlorid and oxychlorid. Oxidizing and chlorinating agents convert it into  $SnCl_4$ . It is a strong reducing agent.

**Stannic Chlorid**—*Bichlorid*—*Liquid of Libavius*— $SnCl_4$ —259.7—is formed by acting on  $Sn$  or  $SnCl_2$  with  $Cl$ , or by heating  $Sn$  in aqua regia. It is a fuming yellowish liquid; sp. gr. 2.28; boils at  $120^\circ$  ( $248^\circ F.$ ).

**Analytical Characters.**—**STANNOUS.**—(1.) Potash or soda: white ppt.; soluble in excess; the solution deposits  $Sn$  when boiled. (2.) Ammonium hydrate: white ppt.; insoluble in excess; turns olive-brown when the liquid is boiled. (3.) Hydrogen sulphid: dark brown ppt.; soluble in  $KHO$ , alkaline sulphids, and hot  $H_2O$ . (4.) Mercuric chlorid: white ppt.; turning gray and black. (5.) Auric chlorid: purple or brown ppt., in presence of small quantity of  $HNO_3$ . (6.) Zinc: deposit of  $Sn$ .

**STANNIC.**—(1.) Potash or ammonia: white ppt.; soluble in excess. (2.) Hydrogen sulphid: yellow ppt.; soluble in alkalies, alkaline sulphids, and hot  $HCl$ . (3.) Sodium hyposulphite: yellow ppt. when heated.

## VIII. PLATINUM GROUP.

### PALLADIUM. PLATINUM.

## IX. RHODIUM GROUP.

### RHODIUM. RUTHENIUM. IRIIDIUM.

The elements of these two groups, together with osmium, are usually classed as "metals of the platinum ores." They all form hydrates (or salts representing them) having acid properties. Osmium has been removed, because the relations existing between its compounds, and those of molybdenum and tungsten, are much closer than those which they exhibit to the compounds of these groups. The separation of the remaining platinum metals into two groups is based upon resemblances in the composition of their compounds, as shown in the following table:

#### *Chlorids.*

$PdCl_2$ .....	$PtCl_2$	$RhCl_2$ .....	$RuCl_2$ .....	?
$PdCl_4$ .....	$PtCl_4$	.....	$RuCl_4$ .....	$IrCl_4$
.....	.....	$Rh_2Cl_6$ .....	$Ru_2Cl_6$ .....	$Ir_2Cl_6$

*Oxids.*

PdO.....	PtO
-----	-----
PdO <sub>2</sub> .....	PtO <sub>2</sub>
-----	-----
-----	-----

RhO.....	RuO.....	IrO
Rh <sub>2</sub> O <sub>3</sub> .....	Ru <sub>2</sub> O <sub>3</sub> .....	Ir <sub>2</sub> O <sub>3</sub>
RhO <sub>2</sub> .....	RuO <sub>2</sub> .....	IrO <sub>2</sub>
RhO <sub>3</sub> .....	RuO <sub>3</sub> .....	IrO <sub>3</sub>
-----	RuO <sub>4</sub> .....	-----

**PLATINUM.**

*Symbol* = **Pt**—*Atomic weight* = 194.4—*Molecular weight* = 388.8  
(?)—*Sp. gr.* = 21.1–21.5.

**Occurrence.**—Free and alloyed with Os, Ir, Pd, Rh, Ru, Fe, Pb, Au, Ag, and Cu.

**Properties.**—The compact metal has a silvery lustre; softens at a white heat; may be welded; fuses with difficulty; highly malleable, ductile and tenacious. **Spongy platinum** is a grayish, porous mass, formed by heating the double chlorid of Pt and NH<sub>4</sub>. **Platinum black** is a black powder, formed by dissolving PtCl<sub>2</sub> in solution of potash, and heating with alcohol. Both platinum black and platinum sponge are capable of condensing large quantities of gas, and act as indirect oxidants.

Platinum is not oxidized by air or O; it combines directly with Cl, P, As, Si, S, and C; is not attacked by acids, except aqua regia, in which it dissolves as PtCl<sub>4</sub>. It forms fusible alloys when heated with metals or reducible metallic oxids. It is attacked by mixtures liberating Cl, and by contact with heated phosphates, silicates, hydrates, nitrates, or carbonates of the alkaline metals.

**Platinic chlorid**—*Tetrachlorid* or *perchlorid* of platinum—**PtCl<sub>4</sub>**—336.4—is obtained by dissolving Pt in aqua regia, and evaporating. It crystallizes in very soluble, deliquescent, yellow needles. Its solution is used as a test for compounds of NH<sub>4</sub> and K.

**PALLADIUM.**

*Symbol* = **Pd**—*Atomic weight* = 105.7—*Molecular weight* = 211.4  
(?)—*Sp. gr.* = 11.5.

A white metal, resembling Pt in appearance; but usually exhibiting a reddish reflection. It is harder, much lighter, and more readily fusible than Pt. It dissolves in HNO<sub>3</sub>, as Pd(NO<sub>3</sub>)<sub>2</sub>. It possesses the property of occluding gases, notably hydrogen, in a much more marked degree than any other metal. One volume of palladium condenses 640 volumes of hydrogen at 100° (212° F.).

**RHODIUM.**

*Symbol* = **Rh** — *Atomic weight* = 104.1 — *Molecular weight* = 208.2 (?) — *Sp. gr.* = 11.4.

A hard, malleable, white metal, insoluble in aqua regia. Its compounds are mostly red, whence its name, from *rhodon*, a rose.

**RUTHENIUM.**

*Symbol* = **Ru** — *Atomic weight* = 104.2 — *Sp. gr.* = 11.4.

A hard, brittle, very difficultly fusible metal, not dissolved by aqua regia, occurring in small quantity in platinum ores.

**IRIDIUM.**

*Symbol* = **Ir** — *Atomic weight* = 192.7 — *Sp. gr.* = 22.3.

A hard, brittle metal which occurs in nature in platinum ores, and alloyed with osmium. It is not attacked by aqua regia. It is used to make an alloy with platinum, which is less fusible, more rigid, harder, denser, and less readily attacked chemically than pure platinum.

## CLASS IV.—BASYLOUS ELEMENTS.

Elements whose Oxids Unite with Water to form Bases ; never to form Acids. Which form Oxysalts.

## I. SODIUM GROUP.

## Alkali Metals.

LITHIUM—SODIUM—POTASSIUM—RUBIDIUM—CÆSIUM—SILVER.

Each of the elements of this group forms a single chlorid,  $MCl$ , and one or more oxids, the most stable of which has the composition  $M_2O$  ; they are, therefore, univalent. Their hydrates,  $MHO$ , are more or less alkaline and have markedly basic characters. Silver resembles the other members of the group in chemical properties, although it does not in physical characters.

## LITHIUM.

*Symbol* = **Li**—*Atomic weight* = 7—*Molecular weight* = 14 (?)—*Sp. gr.* = 0.589—*Fuses at* 180° (356° F.)—*Discovered by Arfvedson in 1817*—*Name from λίθος* = stony.

**Occurrence.**—Widely distributed in small quantity ; in many minerals and mineral waters ; in the ash of tobacco and other plants ; in the milk and blood.

**Properties.**—A silver-white, ductile, volatile metal ; the lightest of the solid elements ; burns in air with a crimson flame ; decomposes  $H_2O$  at ordinary temperatures, without igniting.

**Lithium Oxid**— **$Li_2O$** —30—is a white solid, formed by burning Li in dry O. It dissolves slowly in  $H_2O$  to form lithium hydrate— **$LiHO$** .

**Lithium Chlorid**— **$LiCl$** —43.5—crystallizes in deliquescent, regular octahedra ; very soluble in  $H_2O$  and in alcohol.

**Lithium Bromid**—**Lithii bromidum (U. S.)**— **$LiBr$** —87—is formed by decomposing lithium sulphate with potassium bromid ; or by saturating a solution of  $HBr$  with lithium carbonate. It crystallizes in very deliquescent, soluble needles.

**Lithium Carbonate**—**Lithii carbonas (U. S.; Br.)**— **$Li_2CO_3$** —74—is a white, sparingly soluble, alkaline, amorphous powder. With uric acid it forms lithium urate (*q. v.*).

**Analytical Characters.**—(1.) Ammonium carbonate : white ppt. in concentrated solutions ; not in dilute solutions, or in presence of ammoniacal salts. (2.) Sodium phosphate : white ppt. in neutral or alkaline solution : soluble in acids and in solutions of ammoniacal salts. (3.) It colors the Bunsen flame red ; and exhibits a spectrum of two lines— $\lambda = 6705$  and  $6102$  (Fig. 16, No. 4).

## SODIUM.

*Symbol = Na (NATRIUM) — Atomic weight = 23 — Molecular weight = 46 (?) — Sp. gr. = 0.972 — Fuses at 95.6 (204.1 F.) — Boils at 742 (1368 F.) — Discovered by Davy, 1807.*

**Occurrence.**—As chlorid, very abundantly and widely distributed; also as carbonate, nitrate, sulphate, borate, etc.

**Preparation.**—By heating a mixture of dry sodium carbonate, chalk, and charcoal to whiteness in iron retorts, connected with suitable condensers, in which the distilled metal collects, under a layer of coal naphtha.

**Properties.**—A silver-white metal, rapidly tarnished, and coated with a yellow film in air. Waxy at ordinary temperatures; volatile at a white heat, forming a colorless vapor, which burns in air with a yellow flame.

In air it is gradually oxidized from the surface, but may be kept in closed vessels, without the protection of a layer of naphtha. It decomposes  $H_2O$ , sometimes explosively. Burns with a yellow flame. Combines directly with Cl, Br, I, S, P, As, Pb, and Sn.

**Oxids.**—Two oxids are known: Sodium monoxid— $Na_2O$ —a grayish-white mass; formed when Na is burnt in dry air, or by the action of Na on NaHO. Sodium dioxid— $Na_2O_2$ —a white solid, formed when Na is heated in dry air to 200° (392 F.).

**Sodium hydrate—Sodium hydroxid—Caustic Soda—Soda (U. S.) —Soda caustica (Br.)—NaHO—40**—is formed: (1) when  $H_2O$  is decomposed by Na; (2) by decomposing sodic carbonate by calcium hydrate:  $Na_2CO_3 + CaH_2O_2 = CO_2Ca + 2NaHO$  (soda by lime); (3) in the same manner as in (2), using barium hydrate in place of lime (soda by baryta). It frequently contains considerable quantities of As.

It is an opaque, white, fibrous, brittle solid; fusible below redness; sp. gr. 2.00; very soluble in  $H_2O$ , forming strongly alkaline and caustic solutions (soda lye and liq. sodæ). When exposed to air, solid or in solution, it absorbs  $H_2O$  and  $CO_2$ , and is converted into carbonate. Its solutions attack glass.

**Sodium chlorid—Common salt—Sea salt—Table salt—Sodii chloridum (U. S., Br.)—NaCl—58.5**—occurs very abundantly in nature, deposited in the solid form as rock salt; in solution in all natural waters, especially in sea and mineral spring waters; in suspension in the atmosphere; and as a constituent of almost all animal and vegetable tissues and fluids. It is formed in an infinite variety of chemical reactions. It is obtained from rock salt, or from the waters of the sea or of saline springs; and is the

source from which all the Na compounds are usually obtained, directly or indirectly.

It crystallizes in anhydrous, white cubes, or octahedra : sp. gr. 2.078 ; fuses at a red heat, and crystallizes on cooling ; sensibly volatile at a white heat ; quite soluble in  $\text{H}_2\text{O}$ , the solubility varying but slightly with the variations of temperature. Dilute solutions yield almost pure ice on freezing. It is precipitated from concentrated solutions by  $\text{HCl}$ . It is insoluble in absolute alcohol ; sparingly soluble in dilute spirit. It is decomposed by  $\text{H}_2\text{SO}_4$  with formation of  $\text{HCl}$  and sodium sulphate :  $2\text{NaCl} + \text{H}_2\text{SO}_4 = 2\text{HCl} + \text{Na}_2\text{SO}_4$ .

PHYSIOLOGICAL.—Sodium chlorid exists in every animal tissue and fluid, and is present in the latter, especially the blood, in tolerably constant proportion. It is introduced with the food, either as a constituent of the alimentary substances, or as a condiment. In the body it serves to aid the phenomena of osmosis, and to maintain the solution of the albuminoids. It is probable, also, that it is decomposed in the gastric mucous membrane with formation of free hydrochloric acid.

It is discharged from the economy by all the channels of elimination, notably by the urine, when the supply by the food is maintained. If, however, the food contain no salt, it disappears from the urine before it is exhausted from the blood.

The amount of  $\text{Cl}$  (mainly in the form of  $\text{NaCl}$ ) voided by a normal male adult in 24 hours is about 10 grams (154 grains), corresponding to 16.5 grams (255 grains) of  $\text{NaCl}$ . When normal or excessive doses are taken, the amount eliminated by the urine is less than that taken in ; when small quantities are taken, the elimination is at first in excess of the supply. The hourly elimination increases up to the seventh hour, when it again diminishes. The amount of  $\text{NaCl}$  passed in the urine is less than the normal in acute, febrile diseases ; in intermittent fever it is diminished during the paroxysms, but not during the intervals. In diabetes it is much increased, sometimes to 29 grams (448 grains) per diem.

*Quantitative determination of chlorids in urine.*—The process is based upon the formation of the insoluble silver chlorid, and upon the formation of the brown silver chromate in neutral liquids, in the absence of soluble chlorids. The solutions required are : (1) *A solution of silver nitrate* of known strength, made by dissolving 29.075 grams of pure, fused silver nitrate (see p. 193) in a litre of water ; (2) *a solution of neutral potassium chromate*.

To conduct the determination, 5–10 c.c. of the urine are placed in a platinum basin, 2 grams of sodium nitrate (free from chlorid) are added : the whole is evaporated to dryness over the water-bath, and the residue heated gradually until a colorless, fused

mass remains. This, on cooling, is dissolved in  $H_2O$ , the solution placed in a small beaker, treated with pure, dilute  $HNO_3$  to faintly acid reaction, and neutralized with calcium carbonate. Two or three drops of the chromate solution are added, and then the silver solution from a burette, during constant stirring of the liquid in the beaker, until a faint reddish tinge remains permanent. Each c.c. of the silver solution used represents 10 milligrams  $NaCl$  (or 6.065 milligrams  $Cl$ ) in the amount of urine used.

*Example.*—5 c.c. urine used; 6 c.c. silver solution added; 1,200 c.c. urine passed in 24 hours :  $\therefore \frac{0.01 \times 6}{5} \times 1,200 = 14.4$  grams  $NaCl$  in 24 hours.

If the urine contain iodids or bromids, they must be removed, by acidulating the solution or the residue of incineration with  $H_2SO_4$ , removing the iodine or bromine by shaking with carbon disulphid, neutralizing the aqueous solution with calcium carbonate and proceeding as above.

**Sodium Bromid**—**Sodii bromidum (U. S.)**— **$NaBr$ —103**—is formed by dissolving  $Br$  in solution of  $NaHO$  to saturation; evaporating; calcining at dull redness; redissolving; filtering; and crystallizing. It crystallizes in anhydrous cubes; quite soluble in  $H_2O$ , soluble in alcohol.

**Sodium Iodid**—**Sodii iodidum (U. S.)**— **$NaI$ —150**—is prepared by heating together  $H_2O$ ,  $Fe$ , and  $I$  in fine powder; filtering; adding an equivalent quantity of sodium sulphate, and some slacked lime; boiling; decanting and evaporating. Crystallizes in anhydrous cubes; very soluble in  $H_2O$ ; soluble in alcohol.

**Sodium Nitrate**—**Cubic or Chili saltpetre**—**Sodii nitras (U. S.)**— **$Sodæ nitras (Br.)$ — $NaNO_3$ —85**—occurs in natural deposits in Chili and Peru. It crystallizes in anhydrous, deliquescent rhombohedra; cooling and somewhat bitter in taste; fuses at  $310$  ( $590^\circ F.$ ); very soluble in  $H_2O$ . Heated with  $H_2SO_4$ , it is decomposed, yielding  $HNO_3$  and hydrosodic sulphate:  $H_2SO_4 + NaNO_3 = HNaSO_4 + HNO_3$ . This reaction is that used for obtaining  $HNO_3$ .

**Sulphates.**—**Monosodic sulphate**—*Hydrosodic sulphate*—*Acid sodium sulphate*—**Bisulphate**— **$HNaSO_4$ —120**—crystallizes in long, four-sided prisms; is unstable and decomposed by air,  $H_2O$  or alcohol, into  $H_2SO_4$  and  $Na_2SO_4$ . Heated to dull redness it is converted into sodium pyrosulphate,  $Na_2S_2O_7$ , corresponding to Nordhausen sulphuric acid.

**Disodic Sulphate**—*Sodic sulphate*—*Neutral sodium sulphate*—**Glauber's salt**—**Sodii sulphas (U. S.)**— **$Sodæ sulphas (Br.)$ — $Na_2SO_4 + n Aq$ —142 +  $n$  18**—occurs in nature in solid deposits, and in solution in natural waters. It is obtained as a secondary product in the manufacture of  $HCl$ , by the action of  $H_2SO_4$  on  $NaCl$ ,

the decomposition occurring according to the equation :  $2 \text{NaCl} + \text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + 2 \text{HCl}$ , if the temperature be raised sufficiently. At lower temperatures, the monosodic salt is produced, with only half the yield of  $\text{HCl}$  :  $\text{NaCl} + \text{H}_2\text{SO}_4 = \text{NaHSO}_4 + \text{HCl}$ .

It crystallizes with 7 Aq. from saturated or supersaturated solutions at 5° (41° F.); or, more usually, with 10 Aq. As usually met with it is in large, colorless, oblique rhombic prisms with 10 Aq; which effloresce in air, and gradually lose all their Aq. It fuses at 33° (91° F.) in its Aq. which it gradually loses. If fused at 33° (91° F.), and allowed to cool, it remains liquid in *super-saturated* solution, from which it is deposited, the entire mass becoming solid, on contact with a small particle of solid matter. It dissolves in  $\text{HCl}$  with considerable diminution of temperature.

**PHYSIOLOGICAL.**—The neutral sulphates of Na and K seem to exist in small quantity in all animal tissues and fluids, with the exception of milk, bile, and gastric juice; certainly in the blood and urine. They are partially introduced with the food, and partly formed as a result of the metamorphosis of those constituents of the tissues which contain S in organic combination.

The principal elimination of the sulphates is by the urine. All the sulphuric acid in the urine is not in simple combination with the alkali metals. A considerable amount exists in the form of the alkaline salts of conjugate, monobasic, ether acids, which, on decomposition, yield an aromatic organic compound. The amount of  $\text{H}_2\text{SO}_4$  discharged by the urine in 24 hours, in the form of alkaline sulphates, is from 2.5 to 3.5 grams (38.5–54 grains). That eliminated in the salts of conjugate acids, 0.617 to 0.094 gram (9.5–1.5 grains).

**Sodium Sulphite**—*Sodii sulphis* (U. S.)— $\text{Na}_2\text{SO}_3 + 7 \text{Aq}$ —126 + 126—is formed by passing  $\text{SO}_2$  over crystallized  $\text{Na}_2\text{CO}_3$ . It crystallizes in efflorescent, oblique prisms; quite soluble in  $\text{H}_2\text{O}$ , forming an alkaline solution. It acts as a reducing agent.

**Sodium Thiosulphate**—*Sodium hyposulphite*—*Sodii hyposulphis* (U. S.)— $\text{Na}_2\text{S}_2\text{O}_3 + 5 \text{Aq}$ —158 + 90—is obtained by dissolving S in hot concentrated solution of  $\text{Na}_2\text{SO}_3$ , and crystallizing.

It forms large, colorless, efflorescent prisms; fuses at 45° (113° F.); very soluble in  $\text{H}_2\text{O}$ ; insoluble in alcohol. Its solutions precipitate alumina from solutions of Al salts, without precipitating Fe or Mn; they dissolve many compounds insoluble in  $\text{H}_2\text{O}$ ; cuprous hydrate, iodids of Pb, Ag and Hg, sulphates of Ca and Pb. It acts as a disinfectant and antiseptic.  $\text{H}_2\text{SO}_4$  and most other acids decompose  $\text{Na}_2\text{S}_2\text{O}_3$  according to the equation :  $\text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + \text{SO}_2 + \text{S} + \text{H}_2\text{O}$ . Oxalic, and a few other acids, decompose the thiosulphate with formation of  $\text{H}_2\text{S}$  as well as  $\text{SO}_2$  and S.

**Silicates.**—Quite a number of silicates of Na are known. If

silica and  $\text{Na}_2\text{CO}_3$  be fused together, the residue extracted with  $\text{H}_2\text{O}$ , and the solution evaporated, a transparent, glass-like mass, soluble in warm water, remains; this is **soluble glass** or **water glass**. Exposed to air in contact with stone, it becomes insoluble, and forms an impermeable coating.

**Phosphates.**—**Trisodic Phosphate**—*Basic sodium phosphate*— $\text{Na}_3\text{PO}_4 \cdot 12 \text{ Aq}$ —164 + 216—is obtained by adding  $\text{NaHO}$  to disodic phosphate solution, and crystallizing. It forms six-sided prisms; quite soluble in  $\text{H}_2\text{O}$ . Its solution is alkaline, and, on exposure to air, absorbs  $\text{CO}_2$ , with formation of  $\text{HNa}_2\text{PO}_4$  and  $\text{Na}_2\text{CO}_3$ .

**Disodic Phosphate**—*Hydro-disodic phosphate*—*Neutral sodium phosphate*—*Phosphate of soda*—**Sodii phosphas (U. S.)**—**Sodæ phosphas (Br.)**— $\text{HNa}_2\text{PO}_4 \cdot 12 \text{ Aq}$ —142 + 216—is obtained by converting tricalcic phosphate into monocalcic phosphate, and decomposing that salt with sodium carbonate:  $\text{Ca}(\text{PO}_4\text{H}_2)_2 + 2\text{Na}_2\text{CO}_3 = \text{CaCO}_3 + \text{H}_2\text{O} + \text{CO}_2 + 2\text{HNa}_2\text{PO}_4$ .

Below 30° (86° F.) it crystallizes in oblique rhombic prisms, with 12 Aq; at 33° (91.4° F.) it crystallizes with 7 Aq. The salt with 12 Aq effloresces in air, and parts with 5 Aq; and is very soluble in  $\text{H}_2\text{O}$ . The salt with 7 Aq is not efflorescent, and less soluble in  $\text{H}_2\text{O}$ . Its solutions are faintly alkaline.

**Monosodic Phosphate**—*Acid sodium phosphate*— $\text{H}_2\text{NaPO}_4 \cdot \text{Aq}$ —120 + 18—crystallizes in rhombic prisms; forming acid solutions. At 100° (212° F.) it loses Aq; at 200° (392° F.) it is converted into acid pyrophosphate,  $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$ ; and at 204° (399.2° F.) into the **metaphosphate**,  $\text{NaPO}_3$ .

**PHYSIOLOGICAL.**—All the sodium phosphates exist, accompanied by the corresponding K salts, in the animal economy. The disodic and dipotassic phosphates are the most abundant, and of these two the former. They exist in every tissue and fluid of the body, and are more abundant in the fluids of the carnivora than in those of the herbivora. In the blood, in which the Na salt predominates in the plasma, and the K salt in the corpuscles, they serve to maintain an alkaline reaction. With strictly vegetable diet the proportion of phosphates in the blood diminishes, and that of the carbonates (the predominating salts in the blood of the herbivora) increases.

The monosodic and monopotassic phosphates exist in the urine, the former predominating, and to their presence the acid reaction of that fluid is largely due. They are produced by decomposition of the neutral salts by uric acid. The urine of the herbivora, whose blood is poor in phosphates, is alkaline in reaction.

The greater part of the phosphates in the body are introduced with the food. A portion is formed in the economy by the oxidation of phosphorized organic substances, the lecithins.

**Disodic Tetraborate**—*Sodium pyroborate*—*Borate of sodium*—**Borax**—*Tincal*—**Sodii boras** (U. S.)—**Borax** (Br.)— $\text{Na}_2\text{B}_4\text{O}_7 + 10 \text{ Aq}$ — $202 + 180$ —is prepared by boiling boric acid with  $\text{Na}_2\text{CO}_3$  and crystallizing. It crystallizes in hexagonal prisms with 10 Aq; permanent in moist air, but efflorescent in dry air; or in regular octahedra with 5 Aq, permanent in dry air. Either form, when heated, fuses in its Aq, swells considerably; at a red heat becomes anhydrous; and, on cooling, leaves a transparent, glass-like mass. When fused, it is capable of dissolving many metallic oxids, forming variously colored masses, hence its use as a flux and in blow-pipe analysis.

**Sodium Hypochlorite**— $\text{NaClO}$ —74.5—only known in solution—**Liq. sodæ chloratæ** (U. S.; Br.) or **Labarraque's solution**—obtained by decomposing a solution of chlorid of lime by  $\text{Na}_2\text{CO}_3$ . It is a valuable source of Cl, and is used as a bleaching and disinfecting agent.

**Sodium Manganate**— $\text{Na}_2\text{MnO}_4 + 10 \text{ Aq}$ — $164 + 180$ —faintly colored crystals, forming a green solution with  $\text{H}_2\text{O}$ —**Condy's green disinfectant**.

**Sodium Permanganate**— $\text{Na}_2\text{Mn}_2\text{O}_8$ —282—prepared in the same way as the K salt (*q. v.*), which it resembles in its properties. It enters into the composition of **Condy's fluid**, and of "**chlorozone**," which contains  $\text{Na}_2\text{Mn}_2\text{O}_8$  and  $\text{NaClO}$ .

**Sodium Acetate**—**Sodii acetat** (U. S.)—**Sodæ acetat** (Br.)— $\text{NaC}_2\text{H}_3\text{O}_2 + 3 \text{ Aq}$ — $82 + 54$ —crystallizes in large, colorless prisms; acid and bitter in taste; quite soluble in  $\text{H}_2\text{O}$ ; soluble in alcohol; loses its Aq in dry air, and absorbs it again from moist air. Heated with soda lime, it yields marsh gas. The anhydrous salt, heated with  $\text{H}_2\text{SO}_4$ , yields glacial acetic acid.

**Carbonates.**—Three are known:  $\text{Na}_2\text{CO}_3$ ;  $\text{HNaCO}_3$ , and  $\text{H}_2\text{Na}_4(\text{CO}_3)_3$ .

**Disodic Carbonate**—*Neutral carbonate*—*Soda*—**Sal soda**—**Washing soda**—**Soda crystals**—**Sodii carbonas** (U. S.)—**Sodæ carbonas** (Br.)— $\text{Na}_2\text{CO}_3 + 10 \text{ Aq}$ — $106 + 180$ —industrially the most important of the Na compounds, is manufactured by Leblanc's or Solvay's processes; or from *cryolite*, a native fluorid of Na and Al.

Leblanc's process, in its present form, consists of three distinct processes: (1.) The conversion of  $\text{NaCl}$  into the sulphate, by decomposition by  $\text{H}_2\text{SO}_4$ . (2.) The conversion of the sulphate into carbonate, by heating a mixture of the sulphate with calcium carbonate and charcoal. The product of this reaction, known as **black ball soda**, is a mixture of sodium carbonate, with charcoal and calcium sulphid and oxid. (3.) The purification of the product obtained in (2). The ball black is broken up, disintegrated by steam, and lixiviated. The solution on evaporation yields the **soda salt** or **soda of commerce**.

Of late years Leblanc's process has been in great part replaced by Solvay's method, or the *ammonia process*, which is more economical, and yields a purer product. In this process sodium chlorid and ammonium bicarbonate react upon each other, with production of the sparingly soluble sodium bicarbonate, and the very soluble ammonium chlorid. The sodium bicarbonate is then simply collected, dried, and heated, when it is decomposed into  $\text{Na}_2\text{CO}_3$ ,  $\text{H}_2\text{O}$ , and  $\text{CO}_2$ .

The anhydrous carbonate, *Sodii carbonas exsiccatus* (U. S.),  $\text{Na}_2\text{CO}_3$ , is formed, as a white powder, by calcining the crystals. It fuses at dull redness, and gives off a little  $\text{CO}_2$ . It combines with and dissolves in  $\text{H}_2\text{O}$  with elevation of temperature.

The crystalline sodium carbonate,  $\text{Na}_2\text{CO}_3 \cdot 10 \text{ Aq.}$  forms large rhombic crystals, which effloresce rapidly in dry air; fuse in their Aq. at  $34^\circ$  ( $93.2^\circ \text{ F.}$ ); are soluble in  $\text{H}_2\text{O}$ , most abundantly at  $38^\circ$  ( $100.4^\circ \text{ F.}$ ). The solutions are alkaline in reaction.

**Monosodic Carbonate**—*Hydrosodic carbonate*—**Bicarbonate of soda**—*Acid carbonate of soda*—*Vichy salt*—**Sodii bicarbonas** (U. S.)—**Sodæ bicarbonas** (Br.)— $\text{NaHCO}_3$ —84—exists in solution in many mineral waters. It is obtained by the action of  $\text{CO}_2$  upon the disodic salt in the presence of  $\text{H}_2\text{O}$ ; or, as above described, by the Solvay method.

It crystallizes in rectangular prisms, anhydrous and permanent in dry air. In damp air it gives off  $\text{CO}_2$ , and is converted into the **sesquicarbonate**,  $\text{Na}_4\text{H}_2(\text{CO}_3)_3$ . When heated, it gives off  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , and leaves the disodic carbonate. Quite soluble in water; above  $70^\circ$  ( $158^\circ \text{ F.}$ ) the solution gives off  $\text{CO}_2$ . The solutions are alkaline.

**PHYSIOLOGICAL.**—The fact that the carbonates of Na and K are almost invariably found in the ash of animal tissues and fluids, is no evidence of their existence there in life, as the carbonates are produced by the incineration of the Na and K salts of organic acids. There is, however, excellent indirect proof of the existence of the alkaline carbonates in the blood, especially of the herbivora, in the urine of the herbivora at all times, and in that of the carnivora and omnivora, when food rich in the salts of the organic acids, with alkali metals, is taken. The carbonates in the blood are both the mono- and disodic, and potassic; and the carbonic acid in the plasma is held partially in simple solution, and partly in combination in the monometallic carbonates.

**Analytical Characters.**—(1.) Hydrofluosilicic acid: gelatinous ppt., if not too dilute. (2.) Potassium pyroantimonate: in neutral solution and in absence of metals, other than K and Li: a white flocculent ppt.: becoming crystalline on standing. (3.)

Periodic acid in excess : white ppt., in not too dilute solutions.  
(4.) Colors the Bunsen flame yellow, and shows a brilliant double line at  $\lambda = 5895$  and  $5889$  (Fig. 16, No. 2).

### POTASSIUM.

*Symbol = K (KALIUM) — Atomic weight = 39 — Molecular weight = 78 (?) — Sp. gr. = 0.865 — Fuses at 62.5 (144.5 F.) — Boils at 667° (1233° F.) — Discovered by Davy, 1807 — Names from pot ash, and Kali = ashes (Arabic).*

It is prepared by a process similar to that followed in obtaining Na : is a silver-white metal ; brittle at 0° (32° F.) ; waxy at 15° (59° F.) ; fuses at 62.5 (144.5 F.) ; distils in green vapors at a red heat, condensing in cubic crystals.

It is the only metal which oxidizes at low temperatures in dry air, in which it is rapidly coated with a white layer of oxid or hydrate, and frequently ignites, burning with a violet flame. It must, therefore, be kept under naphtha. It decomposes  $H_2O$ , or ice, with great energy, the heat of the reaction igniting the liberated H. It combines with Cl with incandescence, and also unites directly with S, P, As, Sb, and Sn. Heated in  $CO_2$  it is oxidized, and liberates C.

**Oxids.**—Three are known :  $K_2O$  ;  $K_2O_2$  ; and  $K_2O_4$ .

**Potassium Hydrate**—*Potassium hydroxid*—**Potash**—**Potassa**—*Common caustic*—**Potassa (U. S.)**—**Potassa caustica (Br.)**—**KHO**—56—is obtained by a process similar to that used in manufacturing  $NaHO$ . It is purified by solution in alcohol, evaporation and fusion in a silver basin, and casting in silver moulds—**potash by alcohol** ; it is then free from  $KCl$  and  $K_2SO_4$ , but contains small quantities of  $K_2CO_3$ , and frequently As.

It is usually met with in cylindrical sticks, hard, white, opaque, and brittle. The  $KHO$  by alcohol has a bluish tinge, and a smoother surface than the common ; sp. gr. 2.1 ; fuses at dull redness ; is freely soluble in  $H_2O$ , forming a strongly alkaline and caustic liquid ; less soluble in alcohol. In air, solid or in solution, it absorbs  $H_2O$  and  $CO_2$ , and is converted into  $K_2CO_3$ . Its solutions dissolve Cl, Br, I, S, and P. It decomposes the ammoniacal salts, with liberation of  $NH_3$  ; and the salts of many of the metals, with formation of a K salt, and a metallic hydrate. It dissolves the albuminoids, and, when heated, decomposes them with formation of leucin, tyrosin, etc. It oxidizes the carbohydrates with formation of potassium oxalate and carbonate. It decomposes the fats with formation of soft soaps.

**Sulphids.**—Five are known :  $K_2S$ ,  $K_2S_2$ ,  $K_2S_3$ ,  $K_2S_4$ , and  $K_2S_5$  ; also a sulphhydrate :  $KHS$ .

**Potassium Monosulphid**— $\text{K}_2\text{S}$ —110—is formed by the action of  $\text{KHO}$  on  $\text{KHS}$ . **Potassium Disulphid**— $\text{K}_2\text{S}_2$ —142—is an orange-colored solid, formed by exposing an alcoholic solution of  $\text{KHS}$  to the air. **Potassium Trisulphid**— $\text{K}_2\text{S}_3$ —174—a brownish-yellow mass, obtained by fusing together  $\text{K}_2\text{CO}_3$  and  $\text{S}$  in the proportion:  $4\text{K}_2\text{CO}_3 + 10\text{S} = \text{SO}_2 + \text{K}_2\text{S} + 3\text{K}_2\text{S}_3 + 4\text{CO}_2$ . **Potassium Penta-sulphid**— $\text{K}_2\text{S}_5$ —238—is formed, as a brown mass, when  $\text{K}_2\text{CO}_3$  and  $\text{S}$  are fused together in the proportion:  $4\text{K}_2\text{CO}_3 + 16\text{S} = 4\text{CO}_2 + 3\text{K}_2\text{S}_8 + \text{K}_2\text{SO}_4$ . **Liver of Sulphur**—*hepar sulphuris*—**potassii sulphuratum** (**U. S.**; **Br.**)—is a mixture of  $\text{K}_2\text{S}_3$  and  $\text{K}_2\text{S}_5$ .

**Potassium Sulphydrate**— $\text{KHS}$ —72—is formed by saturating a solution of  $\text{KHO}$  with  $\text{H}_2\text{S}$ .

**Potassium Chlorid**.—*Sal digestivum Sylrii*— $\text{KCl}$ —74.5—exists in nature, either pure or mixed with other chlorids; principally as carnallite,  $\text{KCl}$ ,  $\text{MgCl}_2 + 6\text{Aq}$ . It crystallizes in anhydrous, permanent cubes, soluble in  $\text{H}_2\text{O}$ .

**Potassium Bromid**—**Potassii bromidum** (**U. S.**; **Br.**)— $\text{KBr}$ —119—is formed, either by decomposing ferrous bromid by  $\text{K}_2\text{CO}_3$ , or by dissolving  $\text{Br}$  in solution of  $\text{KHO}$ . In the latter case the bromate formed is converted into  $\text{KBr}$ , by calcining the product. It crystallizes in anhydrous cubes or tables; has a sharp, salty taste; very soluble in  $\text{H}_2\text{O}$ , sparingly so in alcohol. It is decomposed by  $\text{Cl}$  with liberation of  $\text{Br}$ .

**Potassium Iodid**—**Potassii iodidum** (**U. S.**; **Br.**)— $\text{KI}$ —166—is obtained by saturating  $\text{KHO}$  solution with  $\text{I}$ , evaporating, and calcining the resulting mixture of iodid and iodate with charcoal. It frequently contains iodate and carbonate. It crystallizes in cubes, transparent if pure; permanent in air; anhydrous; soluble in  $\text{H}_2\text{O}$ , and in alcohol. It is decomposed by  $\text{Cl}$ ,  $\text{HNO}_3$ , and  $\text{HNO}_2$ , with liberation of  $\text{I}$ . It combines with other iodids to form double iodids. Its solutions dissolve iodine and many metallic iodids.

**Potassium Nitrate**—**Nitre**—**Saltpetre**—**Potassii nitras** (**U. S.**)—**Potassæ nitras** (**Br.**)— $\text{KNO}_3$ —101—occurs in nature, and is produced artificially, as a result of the decomposition of nitrogenized organic substances. It is usually obtained by decomposing native  $\text{NaNO}_3$  by boiling solution of  $\text{K}_2\text{CO}_3$  or  $\text{KCl}$ .

It crystallizes in six-sided, rhombic prisms, grooved upon the surface; soluble in  $\text{H}_2\text{O}$ , with depression of temperature; more soluble in  $\text{H}_2\text{O}$  containing  $\text{NaCl}$ ; very sparingly soluble in alcohol; fuses at 350 (662  $^{\circ}\text{F}$ .) without decomposition; gives off  $\text{O}$ , and is converted into nitrite below redness; more strongly heated, it is decomposed into  $\text{N}$ ,  $\text{O}$ , and a mixture of  $\text{K}$  oxids. It is a valuable oxidant at high temperatures; heated with charcoal it deflagrates.

Gunpowder is an intimate mixture of  $\text{KNO}_3$  with S and C, in such proportion that the  $\text{KNO}_3$  yields all the O required for the combustion of the S and C.

**Potassium Chlorate**—*Potassii chloras* (U. S.)—*Potassæ chloras* (Br.)— $\text{KClO}_3$ —122.5—is prepared: (1) by passing Cl through a solution of  $\text{KHO}$ ; (2) by passing Cl over a mixture of milk of lime and  $\text{KCl}$ , heated to  $60^\circ$  ( $140^\circ$  F.). It crystallizes in transparent, anhydrous plates; soluble in  $\text{H}_2\text{O}$ ; sparingly soluble in weak alcohol.

It fuses at  $400$  ( $752$  F.). If further heated, it is decomposed into  $\text{KCl}$  and perchlorate, and at a still higher temperature the perchlorate is decomposed into  $\text{KCl}$  and O:  $2\text{KClO}_3 = \text{KClO}_4 + \text{KCl} + \text{O}_2$  and  $\text{KClO}_4 = \text{KCl} + 2\text{O}_2$ . It is a valuable source of O, and a more active oxidant than  $\text{KNO}_3$ . When mixed with readily oxidizable substances, C, S, P, sugar, tannin, resins, etc., the mixtures explode when subjected to shock. With strong  $\text{H}_2\text{SO}_4$ , it gives off  $\text{Cl}_2\text{O}_4$ , an explosive yellow gas. It is decomposed by  $\text{HNO}_3$  with formation of  $\text{KNO}_3$ ,  $\text{KClO}_4$ , and liberation of Cl and O. Heated with  $\text{HCl}$  it gives off a mixture of Cl and  $\text{Cl}_2\text{O}_4$ , the latter acting as an energetic oxidant in solutions in which it is generated.

**Potassium Hypochlorite**— $\text{KClO}$ —90.5—is formed in solution by imperfect saturation of a cooled solution of  $\text{KHO}$  with hypochlorous acid. An impure solution is used in bleaching: *Javelle water*.

**Sulphates**.—**Dipotassic sulphate**—*Potassium sulphate*—*Potassii sulphas* (U. S.)—*Potassæ sulphas* (Br.)— $\text{K}_2\text{SO}_4$ —174—occurs native; in the ash of many plants; and in solution in mineral waters. It crystallizes in right rhombic prisms; hard; permanent in air; salt and bitter in taste; soluble in  $\text{H}_2\text{O}$ .

**Monopotassic Sulphate**—*Hydropotassic sulphate*—*Acid sulphate*— $\text{KHSO}_4$ —136—is formed as a by-product in the manufacture of  $\text{HNO}_3$ . When heated it loses  $\text{H}_2\text{O}$ , and is converted into the **pyrosulphate**,  $\text{K}_2\text{S}_2\text{O}_7$ , which, at a higher temperature, is decomposed into  $\text{K}_2\text{SO}_4$  and  $\text{SO}_3$ .

**Dipotassic Sulphite**—*Potassic sulphite*—*Potassii Sulphis* (U. S.)— $\text{K}_2\text{SO}_3$ —158—is formed by saturating solution of  $\text{K}_2\text{CO}_3$  with  $\text{SO}_2$ , and evaporating over  $\text{H}_2\text{SO}_4$ . It crystallizes in oblique rhombohedra; soluble in  $\text{H}_2\text{O}$ . Its solution absorbs O from air, with formation of  $\text{K}_2\text{SO}_4$ .

**Potassium Dichromate**—*Bichromate of potash*—*Potassii bichromas* (U. S.)—*Potassæ bichromas* (Br.)— $\text{K}_2\text{Cr}_2\text{O}_7$ —294.8—is formed by heating a mixture of *chrome iron ore* with  $\text{KNO}_3$ , or  $\text{K}_2\text{CO}_3$  in air; extracting with  $\text{H}_2\text{O}$ ; neutralizing with dilute  $\text{H}_2\text{SO}_4$ ; and evaporating. It forms large, reddish-orange colored prismatic crystals; soluble in  $\text{H}_2\text{O}$ ; fuses below redness, and at

a higher temperature is decomposed into O, potassium chromate, and sesquioxid of chromium. Heated with HCl, it gives off Cl.

**Potassium Permanganate**—Potassii permanganas (U. S.)—Potassæ permanganas (Br.)— $K_2Mn_2O_8$ —314—is obtained by fusing a mixture of manganese dioxid, KHO, and  $KClO_4$ , and evaporating the solution to crystallization;  $K_2MnO_4$  and KCl are first formed; on boiling with  $H_2O$ , the manganate is decomposed into  $K_2Mn_2O_8$ , KHO, and  $MnO_2$ .

It crystallizes in dark prisms, almost black, with greenish reflections, which yield a red powder when broken. Soluble in  $H_2O$ , communicating to it a red color, even in very dilute solution. It is a most valuable oxidizing agent. With organic matter its solution is turned to green, by the formation of the manganate, or deposits the brown sesquioxid of manganese, according to the nature of the organic substance. In some instances the reaction takes place best in the cold, in others under the influence of heat; in some better in acid solutions, in others in alkaline solutions. Mineral reducing agents act more rapidly. Its oxidizing powers render its solutions valuable as disinfectants.

**Potassium Acetate**—Potassii acetas (U. S.)—Potassæ acetas (Br.)— $KC_2H_3O_2$ —110—exists in the sap of plants; and it is by its calcination that the major part of the carbonate of wood ashes is formed. It is prepared by neutralizing acetic acid with  $K_2CO_3$  or  $KHCO_3$ .

It forms crystalline needles, deliquescent, and very soluble in  $H_2O$ ; less soluble in alcohol. Its solutions are faintly alkaline.

**Carbonates.**—Dipotassic Carbonate—Potassic Carbonate—Salt of tartar—Pearl ash—Potassii Carbonas (U. S.)—Potassæ carbonas (Br.)— $K_2CO_3$ —138—exists in mineral waters, and in the animal economy. It is prepared industrially, in an impure form, known as potash or pearlash, from wood ashes, from the molasses of beet-sugar, and from the native Stassfurth chlorid. It is obtained pure by decomposing the monopotassic salt, purified by several recrystallizations, by heat; or by calcining a potassium salt of an organic acid. Thus cream of tartar, mixed with nitre and heated to redness, yields a black mixture of C and  $K_2CO_3$ , called black flux; on extracting which with  $H_2O$ , a pure carbonate, known as salt of tartar, is dissolved.

Anhydrous, it is a white, granular, deliquescent, very soluble powder. At low temperatures it crystallizes with 2 Aq. Its solution is alkaline.

**Monopotassic Carbonate**—Hydropotassic carbonate—Bicarbonate—Potassii bicarbonas—(U. S.)—Potassæ bicarbonas (Br.)— $HKCO_3$ —100—is obtained by dissolving  $K_2CO_3$  in  $H_2O$ , and saturating the solution with  $CO_2$ . It crystallizes in oblique rhombic prisms, much less soluble than the carbonate. In solution, it

is gradually converted into the dipotassic salt when heated, when brought into a vacuum, or when treated with an inert gas. The solutions are alkaline in reaction and in taste, but are not caustic.

The substance used in baking, under the name *salærat*, is this or the corresponding Na salt, usually the latter. Its extensive use in some parts of the country is undoubtedly in great measure the cause of the prevalence of dyspepsia. When used alone in baking, it "raises" the bread by decomposition into carbon dioxid and dipotassic (or disodic) carbonate, the latter producing disturbances of digestion by its strong alkaline reaction.

**Monopotassic oxalate**—*Hydropotassic oxalate*—*Binoxalate of potash*— $\text{HKC}_2\text{O}_4$ —128—forms transparent, soluble, acid needles. It occurs along with the quadroxalate  $\text{HKC}_2\text{O}_4 \cdot \text{H}_2\text{C}_2\text{O}_4 + 2 \text{Aq.}$  in salt of lemon or salt of sorrel, used in straw bleaching, and for the removal of ink-stains, etc. It closely resembles Epsom salt in appearance, and has been fatally mistaken for it.

**Tartrates.**—**Dipotassic tartrate**—*Potassic tartrate*—**Soluble tartar**—*Neutral tartrate of potash*—**Potassii tartras (U. S.)**—**Potassæ tartras (Br.)**— $\text{K}_2\text{C}_4\text{H}_4\text{O}_6$ —226—is prepared by neutralizing the hydropotassic salt with potassium carbonate. It forms a white, crystalline powder, very soluble in  $\text{H}_2\text{O}$ , the solution being dextrogyrous,  $[\alpha]_D = +28.48$ ; soluble in alcohol. Acids, even acetic, decompose its solution, with precipitation of the monopotassic salt.

**Monopotassic tartrate**—*Hydropotassic tartrate*—**Cream of tartar**—**Potassii bitartras (U. S.)**—**Potassæ bitartras (Br.)**— $\text{HKC}_4\text{H}_4\text{O}_6$ —188.—During the fermentation of grape juice, as the porportion of alcohol increases, crystalline crusts collect in the cask. These constitute the **crude tartar**, or **argol**, of commerce, which is composed, in great part, of monopotassic tartrate. The crude product is purified by repeated crystallization from boiling  $\text{H}_2\text{O}$ : digesting the purified tartar with  $\text{HCl}$  at  $20^\circ$  ( $68^\circ \text{F.}$ ); washing with cold  $\text{H}_2\text{O}$ , and crystallizing from hot  $\text{H}_2\text{O}$ .

It crystallizes in hard, opaque (translucent when pure), rhombic prisms, which have an acidulous taste, and are very sparingly soluble in  $\text{H}_2\text{O}$ , still less soluble in alcohol. Its solution is acid, and dissolves many metallic oxids with formation of double tartrates. When boiled with antimony trioxid, it forms tartar emetic.

It is used in the household, combined with monosodic carbonate, in baking, the two substances reacting upon each other to form Rochelle salt, with liberation of carbon dioxid.

**Baking Powders** are now largely used as substitutes for yeast in the manufacture of bread. Their action is based upon the de-

composition of  $\text{HNaCO}_3$  by some salt having an acid reaction, or by a weak acid. In addition to the bicarbonate and flour, or corn-starch (added to render the bulk convenient to handle and to diminish the rapidity of the reaction), they contain cream of tartar, tartaric acid, alum, or acid phosphates. Sometimes ammonium sesquicarbonate is used, in whole or in part, in place of sodium carbonate.

The reactions by which the  $\text{CO}_2$  is liberated are :

1.  $\text{HKC}_4\text{H}_4\text{O}_6 + \text{NaHCO}_3 = \text{NaKC}_4\text{H}_4\text{O}_6 + \text{H}_2\text{O} + \text{CO}_2$   
Monopotassic tartrate.      Monosodic carbonate.      Sodium potassium tartrate.      Water.      Carbon dioxide.
2.  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6 + 2\text{NaHCO}_3 = \text{Na}_2\text{C}_4\text{H}_4\text{O}_6 + 2\text{H}_2\text{O} + 2\text{CO}_2$   
Tartaric acid.      Monosodic carbonate.      Disodic tartrate.      Water.      Carbon dioxide.
3.  $\text{Al}_2(\text{SO}_4)_3, \text{K}_2\text{SO}_4 + 6\text{NaHCO}_3 = \text{K}_2\text{SO}_4 + 3\text{Na}_2\text{SO}_4 + \text{Al}_2\text{H}_6\text{O}_6 + 6\text{CO}_2$   
Aluminium potassium alum.      Monosodic carbonate.      Dipotassic sulphate.      Disodic sulphate.      Aluminium hydrate.      Carbon dioxide.
4.  $\text{Al}_2(\text{SO}_4)_3, (\text{NH}_4)_2\text{SO}_4 + 6\text{NaHCO}_3 = (\text{NH}_4)_2\text{SO}_4 + 3\text{Na}_2\text{SO}_4 + \text{Al}_2\text{H}_6\text{O}_6 + 6\text{CO}_2$   
Aluminium ammonium alum.      Monosodic carbonate.      Diammonic sulphate.      Disodic sulphate.      Aluminium hydrate.      Carbon dioxide.
5.  $\text{Al}_2(\text{SO}_4)_3 + 6\text{NaHCO}_3 = 3\text{Na}_2\text{SO}_4 + \text{Al}_2\text{H}_6\text{O}_6 + 6\text{CO}_2$   
Aluminium sulphate.      Monosodic carbonate.      Disodic sulphate.      Aluminium hydrate.      Carbon dioxide.
6.  $\text{NaH}_2\text{PO}_4 + \text{NaHCO}_3 = \text{Na}_2\text{HPO}_4 + \text{H}_2\text{O} + \text{CO}_2$   
Monosodic phosphate.      Monosodic carbonate.      Disodic phosphate.      Water.      Carbon dioxide.

**Sodium Potassium Tartrate**—*Rochelle salt*—*Sel de seignette*—*Potassii et sodii tartras* (U. S.)—*Soda tartarata* (Br.)— $\text{NaKC}_4\text{H}_4\text{O}_6 + 4 \text{ Aq}$ —210 + 72—is prepared by saturating monopotassic tartrate with disodic carbonate. It crystallizes in large, transparent prisms, which effloresce superficially in dry air, and attract moisture in damp air. It fuses at 70–80 (158–176 F.), and loses 3 Aq at 100 (212 F.). It is soluble in  $\text{H}_2\text{O}$ , the solutions being dextrogyrous,  $[\alpha]_D = + 29.67$ .

**Potassium Antimonyl Tartrate**—*Tartarated antimony*—*Tartar emetic*—*Antimonii et potassii tartras* (U. S.)—*Antimonium tartaratum* (Br.)— $(\text{SbO})\text{KC}_4\text{H}_4\text{O}_6$ —323—is prepared by boiling a mixture of 3 pts.  $\text{Sb}_2\text{O}_3$  and 4 pts.  $\text{HKC}_4\text{H}_4\text{O}_6$  in  $\text{H}_2\text{O}$  for an hour,

filtering, and allowing to crystallize. When required pure, it must be made from pure materials.

It crystallizes in transparent, soluble, right rhombic octahedra, which turn white in air. Its solutions are acid in reaction, have a nauseating, metallic taste, are levogyrous,  $[\alpha]_D = -156.2$ , and are precipitated by alcohol. The crystals contain  $\frac{1}{2}$  Aq, which they lose entirely at 100° (212° F.), and, partially, by exposure to air. It is decomposed by the alkalis, alkaline earths, and alkaline carbonates, with precipitation of  $\text{Sb}_2\text{O}_3$ . The precipitate is redissolved by excess of soda or potash, or by tartaric acid.  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  precipitate corresponding antimonyl compounds from solutions of tartar emetic. It converts mercuric into mercurous chlorid. It forms double tartrates with the tartrates of the alkaloids.

**Potassium Cyanid—Potassii cyanidum (U. S.)—KCN—65**—is obtained by heating a mixture of potassium ferrocyanid and dry  $\text{K}_2\text{CO}_3$ , as long as effervescence continues; decanting and crystallizing.

It is usually met with in dull, white, amorphous masses. Odorless when dry, it has the odor of hydrocyanic acid when moist. It is deliquescent, and very soluble in  $\text{H}_2\text{O}$ ; almost insoluble in alcohol. Its solution is acrid and bitter in taste, with an after-taste of hydrocyanic acid. It is very readily oxidized to the cyanate, a property which renders it valuable as a reducing agent. Solutions of KCN dissolve I,  $\text{AgCl}$ , the cyanids of Ag and Au, and many metallic oxids.

It is actively poisonous, and produces its effects by decomposition and liberation of hydrocyanic acid (*q. v.*).

**Potassium Ferrocyanid—Yellow prussiate of potash—Potassii ferrocyanidum (U.S.)—Potassæ prussias flava (Br.)— $\text{K}_4[\text{Fe}(\text{CN})_6]$  + 3 Aq—367.9 + 54.**—This salt, the source of the other cyanogen compounds, is manufactured by adding organic matter (blood, bones, hoofs, leather, etc.) and iron to  $\text{K}_2\text{CO}_3$  in fusion; or by other processes in which the N is obtained from the residues of the purification of coal-gas, from atmospheric air, or from ammoniacal compounds.

It forms soft, flexible, lemon-yellow crystals, permanent in air at ordinary temperatures. They begin to lose Aq at 60° (140° F.), and become anhydrous at 100° (212° F.). Soluble in  $\text{H}_2\text{O}$ ; insoluble in alcohol, which precipitates it from its aqueous solution. When calcined with  $\text{KHO}$  or  $\text{K}_2\text{CO}_3$ , potassium cyanid and cyanate are formed, and Fe is precipitated. Heated with dilute  $\text{H}_2\text{SO}_4$ , it yields an insoluble white or blue salt, potassium sulphate, and hydrocyanic acid. Its solutions form with those of many of the metallic salts insoluble ferrocyanids; those of Zn, Pb, and Ag are white, cupric ferrocyanid is mahogany-colored, fer-

rous ferrocyanid is bluish-white, ferric ferrocyanid, **Prussian blue**, is dark blue. Blue ink is a solution of Prussian blue in a solution of oxalic acid.

**Potassium Ferricyanid—Red prussiate of potash— $K_3Fe_2(CN)_{12}$** —657.8—is prepared by acting upon the ferrocyanid with chlorine; or, better, by heating the white residue of the action of  $H_2SO_4$  upon potassium ferrocyanid, in the preparation of hydrocyanic acid, with a mixture of 1 vol.  $HNO_3$  and 20 vols.  $H_2O$ ; the *blue* product is digested with  $H_2O$ , and potassium ferrocyanid, the solution filtered and evaporated. It forms red, oblique, rhombic prisms, almost insoluble in alcohol. With solutions of ferrous salts it gives a dark blue precipitate, **Turnbull's blue**.

**Analytical Characters.**—(1.) Platinic chlorid, in presence of  $HCl$ : yellow ppt.; crystalline if slowly formed; sparingly soluble in  $H_2O$ , much less so in alcohol. (2.) Tartaric acid, in not too dilute solution: white ppt.; soluble in alkalies and in concentrated acids. (3.) Hydrofluosilicic acid: translucent, gelatinous ppt.; forms slowly; soluble in strong alkalies. (4.) Perchloric acid: white ppt.; sparingly soluble in  $H_2O$ ; insoluble in alcohol. (5.) Phosphomolybdic acid: white ppt.; forms slowly. (6.) Colors the Bunsen flame violet (the color is only observable through blue glass in presence of  $Na$ ), and exhibits a spectrum of two bright lines:  $\lambda = 7860$  and  $4045$  (Fig. 16, No. 3).

**Action of the Sodium and Potassium Compounds on the Economy.**—The hydrates of  $Na$  and of  $K$ , and in a less degree the carbonates, disintegrate animal tissues, dead or living, with which they come in contact, and, by virtue of this action, act as powerful caustics upon a living tissue. Upon the skin, they produce a soapy feeling, and in the mouth a soapy taste. Like the acids, they cause death, either immediately, by corrosion or perforation of the stomach; or secondarily, after weeks or months, by closure of one or both openings of the stomach, due to thickening, consequent upon inflammation.

The treatment consists in the neutralization of the alkali by an acid, dilute vinegar. Neutral oils and milk are of service, more by reason of their emollient action than for any power they have to neutralize the alkali, by the formation of a soap, at the temperature of the body.

The other compounds of  $Na$ , if the acid be not poisonous, are without deleterious action, unless taken in excessive quantity. Common salt has produced paralysis and death in a dose of half a pound. The neutral salts of  $K$ , on the contrary, are by no means without true poisonous action when taken internally, or injected subcutaneously, in sufficient quantities; causing dysp-

nœa, convulsions, arrest of the heart's action, and death. In the adult human subject, death has followed the ingestion of doses of  $\frac{3}{4}$  ss.— $\frac{3}{4}$  i. of the nitrate, in several instances; doses of  $\frac{3}{4}$  ij.— $\frac{3}{4}$  ij. of the sulphate have also proved fatal.

**Cæsium**—*Symbol* = **Cs**—*Atomic weight* = 132.6; and **Rubidium**—*Symbol* = **Rb**—*Atomic weight* = 85.3—are two rare elements, discovered in 1860 by Kirchhoff and Bunsen while examining spectroscopically the ash of a spring water. They exist in very small quantity in *lepidolite*. They combine with O and decompose  $H_2O$  even more energetically than does K, forming strongly alkaline hydrates.

## SILVER.

*Symbol* = **Ag** (**ARGENTUM**)—*Atomic weight* = 107.9—*Molecular weight* = 216 (?)—*Sp. gr.* = 10.4–10.54—*Fuses at* 1,000 (1,832 F.).

Although silver is usually classed with the "noble metals," it differs from Au and Pt widely in its chemical characters, in which it more closely resembles the alkaline metals.

When pure Ag is required, coin silver is dissolved in  $HNO_3$  and the diluted solution precipitated with HCl. The silver chlorid is washed, until the washings no longer precipitate with silver nitrate; and reduced, either (1) by suspending it in dilute  $H_2SO_4$  in a platinum basin, with a bar of pure Zn, and washing thoroughly, after complete reduction; or (2) by mixing it with chalk and charcoal (AgCl, 100 parts; C, 5 parts;  $CaCO_3$ , 70 parts), and gradually introducing the mixture into a red-hot crucible.

Silver is a white metal; very malleable and ductile; the best known conductor of heat and electricity. It is not acted on by pure air, but is blackened in air containing a trace of  $H_2S$ . It combines directly with Cl, Br, I, S, P, and As. Hot  $H_2SO_4$  dissolves it as sulphate, and  $HNO_3$  as nitrate. The caustic alkalies do not affect it. It alloys readily with many metals; its alloy with Cu is harder than the pure metal.

Silver seems to exist in a number of allotropic modifications, besides that in which it is ordinarily met with. In one of these it is brilliant, metallic, bluish-green in color, and dissolves in  $H_2O$ , forming a deep red solution; in another it has the color of burnished gold, when dry; and in still another it has also a bluish-green color, but is insoluble in water. Very dilute mineral acids immediately convert these modifications into normal gray silver, without evolution of any gas.

**Oxids.**—Three oxids of silver are known:  $Ag_4O$ ,  $Ag_2O$ , and  $Ag_2O_2$ .

**Silver Monoxid**—*Protoxid*—**Argenti oxidum**—(U. S.; Br.)— $Ag_2O$ —231.8—formed by precipitating a solution of silver nitrate with

potash. It is a brownish powder; faintly alkaline and very slightly soluble in  $H_2O$ ; strongly basic. It readily gives up its oxygen. On contact with ammonium hydrate it forms a fulminating powder.

**Chlorid**— $AgCl$ —143.4—formed when  $HCl$  or a chlorid is added to a solution containing silver. It is white; turns violet and black in sunlight; volatilizes at  $260^\circ$  ( $500^\circ F.$ ); sparingly soluble in  $HCl$ ; soluble in solutions of the alkaline chlorids, hyposulphids, and cyanids, and in ammonium hydrate. It crystallizes in octahedra on exposure of its ammoniacal solution.

**Bromid**— $AgBr$ ; and **Iodid**— $AgI$ —are yellowish precipitates, formed by decomposing silver nitrate with potassium bromid and iodid. The former is very sparingly soluble in ammonium hydrate, the latter is insoluble.

**Argentie Nitrate**—**Argenti Nitras** (**U. S.**; **Br.**)— $AgNO_3$ —169.9—is prepared by dissolving  $Ag$  in  $HNO_3$ , evaporating, fusing, and recrystallizing. It crystallizes in anhydrous, right rhombic plates; soluble in  $H_2O$ . The solutions are colorless and neutral. In the presence of organic matter it turns black in sunlight.

The salt, fused and cast into cylindrical moulds, constitutes **lunar caustic**, **lapis infernalis**; **argenti nitras fusa** (**U. S.**). If, during fusion, the temperature be raised too high, it is converted into nitrite,  $O$ , and  $Ag$ ; and if sufficiently heated, leaves pure  $Ag$ .

Dry  $Cl$  and  $I$  decompose it, with liberation of anhydrous  $HNO_3$ . It absorbs  $NH_3$ , to form a white solid,  $AgNO_3 \cdot 3NH_3$ , which gives up its  $NH_3$  when heated. Its solution is decomposed very slowly by  $H$ , with deposition of  $Ag$ .

**Argentie Cyanid**—**Argenti Cyanidum** (**U. S.**)— $AgCN$ —133.9—is prepared by passing  $HCN$  through a solution of  $AgNO_3$ . It is a white, tasteless powder; gradually turns brown in daylight; insoluble in dilute acids; soluble in ammonium hydrate, and in solutions of ammoniacal salts, cyanids, or hyposulphites. The strong mineral acids decompose it with liberation of  $HCN$ .

**Analytical Characters.**—(1.) Hydrochloric acid: white, flocculent ppt.; soluble in  $NH_4HO$ ; insoluble in  $HNO_3$ . (2.) Potash or soda: brown ppt.; insoluble in excess; soluble in  $NH_4HO$ . (3.) Ammonium hydrate, from neutral solutions: brown ppt.; soluble in excess. (4.) Hydrogen sulphid or ammonium sulphhydrate: black ppt.; insoluble in  $NH_4HS$ . (5.) Potassium bromid: yellowish-white ppt.; insoluble in acids, if not in great excess; soluble in  $NH_4HO$ . (6.) Potassium iodid: same as  $KBr$ , but the ppt. is less soluble in  $NH_4HO$ .

**Action on the Economy.**—Silver nitrate acts both locally as a corrosive, and systemically as a true poison. Its local action is due to its decomposition, by contact with organic substances, resulting in the separation of elementary  $Ag$ , whose deposition

causes a black stain, and liberation of free  $\text{HNO}_3$ , which acts as a caustic. When absorbed, it causes nervous symptoms, referable to its poisonous action. The blue coloration of the skin, observed in those to whom it is administered for some time, is due to the reduction of the metal, under the combined influence of light and organic matter; especially of the latter, as the darkening is observed, although it is less intense, in internal organs.

In acute poisoning by silver nitrate, sodium chlorid or white of egg should be given; and, if the case be seen before the symptoms of corrosion are far advanced, emetics.

### AMMONIUM COMPOUNDS.

**The ammonium theory.**—Although the radical ammonium,  $\text{NH}_4$ , has probably never been isolated, its existence in the ammoniacal compounds is almost universally admitted. The ammonium hypothesis is based chiefly upon the following facts: (1) the close resemblance of the ammoniacal salts to those of K and Na; (2) when ammonia gas and an acid gas come together, they unite, *without liberation of hydrogen*, to form an ammoniacal salt; (3) the diatomic anhydrids unite directly with dry ammonia with formation of the ammonium salt of an amido acid:

(4) when solutions of the ammoniacal salts are subjected to electrolysis, a mixture, having the composition  $\text{NH}_3 + \text{H}$  is given off at the negative pole; (5) amalgam of sodium, in contact with a concentrated solution of ammonium chlorid, increases much in volume, and is converted into a light, soft mass, having the lustre of mercury. This ammonium amalgam is decomposed gradually, giving off ammonia and hydrogen in the proportion  $\text{NH}_3 : \text{H}$ ; (6) if the gases  $\text{NH}_3 + \text{H}$ , given off by decomposition of the amalgam, exist there in simple solution, the liberated H would have the ordinary properties of that element. If, on the other hand, they exist in combination, the H would exhibit the more energetic affinities of an element in the nascent state. The hydrogen so liberated is in the nascent state.

**Ammonium Hydrate**—*Caustic ammonia*— $\text{NH}_4\text{HO}$ —35—has never been isolated, probably owing to its tendency to decomposition;  $\text{NH}_4\text{HO} = \text{NH}_3 + \text{H}_2\text{O}$ . It is considered as existing in the so-called aqueous solutions of ammonia. These are colorless liquids; of less sp. gr. than  $\text{H}_2\text{O}$ ; strongly alkaline; and having the taste and odor of ammonia, which gas they give off on exposure to air, and more rapidly when heated. They are neutralized by acids, with elevation of temperature and formation of

ammoniacal salts. The **Aqua ammoniæ** (U. S.) and **Liq. Ammoniæ** (Br.) are such solutions.

**Sulphids.**—Four are known :  $(\text{NH}_4)_2\text{S}$ ;  $(\text{NH}_4)_2\text{S}_2$ ;  $(\text{NH}_4)_2\text{S}_3$ ; and  $(\text{NH}_4)_2\text{S}_5$ ; as well as a sulphydrate  $(\text{NH}_4)\text{HS}$ .

**Ammonium Sulphydrate**— $\text{NH}_4\text{HS}$ —51—is formed, in solution, by saturating a solution of  $\text{NH}_4\text{HO}$  with  $\text{H}_2\text{S}$ ; or, anhydrous, by mixing equal volumes of dry  $\text{NH}_3$  and dry  $\text{H}_2\text{S}$ .

The anhydrous compound is a colorless, transparent, volatile and soluble solid; capable of sublimation without decomposition. The solution, when freshly prepared, is colorless, but soon becomes yellow from oxidation, and formation of ammonium disulphid and hyposulphite, and finally deposits sulphur.

The sulphids and hydrosulphid of ammonium are also formed during the decomposition of albuminoids, and exist in the gases formed in burial vaults, sewers, etc.

**Ammonium Chlorid**—**Sal ammoniac**—**Ammonii chloridum** (U. S.; Br.)— $\text{NH}_4\text{Cl}$ —53.5—is obtained from the ammoniacal water of gas-works. It is a translucent, fibrous, elastic solid; salty in taste, neutral in reaction; volatile without fusion or decomposition; soluble in  $\text{H}_2\text{O}$ . Its solution is neutral, but loses  $\text{NH}_3$  and becomes acid when boiled.

Ammonium chlorid exists in small quantity in the gastric juice of the sheep and dog; also in the perspiration, urine, saliva, and tears.

**Ammonium Bromid**—**Ammonii bromidum** (U. S.)— $(\text{NH}_4)\text{Br}$ —98—is formed either by combining  $\text{NH}_3$  and  $\text{HBr}$ ; by decomposing ferrous bromid with  $\text{NH}_4\text{HO}$ ; or by double decomposition between  $\text{KBr}$  and  $(\text{NH}_4)_2\text{SO}_4$ . It is a white, granular powder, or crystallizes in large prisms, which turn yellow on exposure to air; quite soluble in  $\text{H}_2\text{O}$ ; volatile without decomposition.

**Ammonium Iodid**—**Ammonii iodidum** (U. S.)— $\text{NH}_4\text{I}$ —145—is formed by union of equal volumes of  $\text{NH}_3$  and  $\text{HI}$ ; or by double decomposition of  $\text{KI}$  and  $(\text{NH}_4)_2\text{SO}_4$ . It crystallizes in deliquescent, very soluble cubes.

**Ammonium Nitrate**—**Ammonii nitras** (U. S.)— $(\text{NH}_4)\text{NO}_3$ —80—is prepared by neutralizing  $\text{HNO}_3$  with ammonium hydrate or carbonate. It crystallizes in flexible, anhydrous, six-sided prisms; very soluble in  $\text{H}_2\text{O}$ , with considerable diminution of temperature; fuses at  $150^\circ$  ( $302^\circ \text{F.}$ ), and decomposes at  $210^\circ$  ( $410^\circ \text{F.}$ ), with formation of nitrous oxid:  $(\text{NH}_4)\text{NO}_3 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$ . If the heat be suddenly applied, or allowed to surpass  $250^\circ$  ( $482^\circ \text{F.}$ ),  $\text{NH}_3$ ,  $\text{NO}$ , and  $\text{N}_2\text{O}$  are formed. When fused it is an active oxidant.

**Sulphates.**—**Diammonic Sulphate**—*Ammonic sulphate*—**Ammonii sulphas** (U. S.)— $(\text{NH}_4)_2\text{SO}_4$ —132—is obtained by collecting the distillate from a mixture of ammoniacal gas liquor and lime in  $\text{H}_2\text{SO}_4$ . It forms anhydrous, soluble, rhombic crystals; fuses

at 140° (284° F.), and is decomposed at 200° (392° F.) into  $\text{NH}_3$  and  $\text{H}(\text{NH}_4)\text{SO}_4$ .

**Monoammonic Sulphate**—*Hydroammonic sulphate*—*Bisulphate of ammonia*— $\text{H}(\text{NH}_4)\text{SO}_4$ —115—is formed by the action of  $\text{H}_2\text{SO}_4$  on  $(\text{NH}_4)_2\text{SO}_4$ . It crystallizes in right rhombic prisms, soluble in  $\text{H}_2\text{O}$  and in alcohol.

**Ammonium Acetate**— $(\text{NH}_4)\text{C}_2\text{H}_3\text{O}_2$ —77—is formed by saturating acetic acid with  $\text{NH}_3$ , or with ammonium carbonate. It is a white, odorless, very soluble solid; fuses at 86° (186.8° F.), and gives off  $\text{NH}_3$ ; then acetic acid, and finally acetamid. **Liq. ammonii acetatis**=**Spirit of Mindererus** is an aqueous solution of this salt.

**Carbonates.**—**Diammonic Carbonate**—*Ammonic carbonate*—*Neutral ammonium carbonate*— $(\text{NH}_4)_2\text{CO}_3 + \text{Aq}$ —96+18—has been obtained as a white crystalline solid. In air it is rapidly decomposed into  $\text{NH}_3$  and  $\text{H}(\text{NH}_4)\text{CO}_3$ .

**Monoammonic Carbonate**—*Hydroammonic carbonate*—*Acid carbonate of ammonia*— $\text{H}(\text{NH}_4)\text{CO}_3$ —79—is prepared by saturating a solution of  $\text{NH}_4\text{HO}$  or ammonium sesquicarbonate with  $\text{CO}_2$ . It crystallizes in large, rhombic prisms; quite soluble in  $\text{H}_2\text{O}$ . At 60° (140° F.) it is decomposed into  $\text{NH}_3$  and  $\text{CO}_2$ .

**Ammonium Sesquicarbonate**—**Sal volatile**—**Preston salts**—**Ammonii carbonas (U. S.)**—**Ammonia carbonas (Br.)**— $(\text{NH}_4)_2\text{H}_2(\text{CO}_3)_3$ —254—is prepared by heating a mixture of  $\text{NH}_4\text{Cl}$  and chalk, and condensing the product. It crystallizes in rhombic prisms; has an ammoniacal odor and an alkaline reaction; soluble in  $\text{H}_2\text{O}$ . By exposure to air or by heating its solution, it is decomposed into  $\text{H}_2\text{O}$ ,  $\text{NH}_3$ , and  $\text{H}(\text{NH}_4)\text{CO}_3$ .

**Analytical Characters.**—(1.) Entirely volatile at high temperatures. (2.) Heated with  $\text{KHO}$ , the ammoniacal compounds give off  $\text{NH}_3$ , recognizable: (a) by changing moist red litmus to blue; (b) by its odor; (c) by forming a white cloud on contact with a glass rod moistened with  $\text{HCl}$ . (3.) With platinic chlorid: a yellow, crystalline ppt. (4.) With hydrosodic tartrate, in moderately concentrated and neutral solution: a white crystalline ppt.

**Action on the Economy.**—Solutions of the hydrate and carbonate act upon animal tissues in the same way as the corresponding  $\text{Na}$  and  $\text{K}$  compounds. They, moreover, disengage  $\text{NH}_3$ , which causes intense dyspnoea, irritation of the air-passages, and suffocation.

The treatment indicated is the neutralization of the alkali by a dilute acid. Usually the vapor of acetic acid or of dilute  $\text{HCl}$  must be administered by inhalation.

## II. THALLIUM GROUP.

## THALLIUM.

*Symbol*=**Tl**—*Atomic weight*=203.7—*Sp. gr.*=11.8-11.9—*Fuses at* 294° (561° F.)—*Discovered by Crookes* (1861).

A rare element, first obtained from the deposits in flues of sulphuric acid factories, in which pyrites from the Hartz were used. It resembles Pb in appearance and in physical properties, but differs entirely from that element in its chemical characters. It resembles Au in being univalent and trivalent, but differs from it, and resembles the alkali metals in being readily oxidized, in forming alums, and in forming no acid hydrate. It differs from the alkali metals in the thallic compounds, which contain  $Tl^3$ . It is characterized spectroscopically by a bright green line— $\lambda=5349$ .

## III. CALCIUM GROUP.

*Metals of the Alkaline Earths.*

## CALCIUM—STRONTIUM—BARIUM.

The members of this group are bivalent in all their compounds; each forms two oxids: MO and  $MO_2$ ; each forms a hydrate, having well marked basic characters.

## CALCIUM.

*Symbol*=**Ca**—*Atomic weight*=40—*Molecular weight*=80 (?)—*Sp. gr.*=1.984—*Discovered by Davy in 1808*—*Name from calx*=lime.

Occurs only in combination, as limestone, marble, chalk ( $CaCO_3$ ); gypsum, selenite, alabaster ( $CaSO_4$ ), and many other minerals. In bones, egg-shells, oyster-shells, etc., as  $Ca_3(PO_4)_2$  and  $CaCO_3$ , and in many vegetable structures.

The element is a hard, yellow, very ductile, and malleable metal; fusible at a red heat; not sensibly volatile. In dry air it is not altered, but is converted into  $CaH_2O_2$  in damp air; decomposes  $H_2O$ ; burns when heated in air.

**Calcium Monoxid**—**Quick lime**—**Lime**—**Calx** (U. S.; Br.)—**CaO**—56—is prepared by heating a native carbonate (limestone); or, when required pure, by heating a carbonate, prepared by precipitation.

It occurs in white or grayish, amorphous masses; odorless; alkaline; caustic; almost infusible; sp. gr. 2.3. With  $H_2O$  it gives off great heat and is converted into the hydrate (slacking). In air it becomes air-slacked, falling into a white powder, having the composition  $CaCO_3$ ,  $CaH_2O_2$ .

**Calcium Hydrate**—Slacked lime—*Calcis hydras* (Br.)— $\text{CaH}_2\text{O}_2$ —74—is formed by the action of  $\text{H}_2\text{O}$  on  $\text{CaO}$ . If the quantity of  $\text{H}_2\text{O}$  used be one-third that of the oxid, the hydrate remains as a dry, white, odorless powder; alkaline in taste and reaction; more soluble in cold than in hot  $\text{H}_2\text{O}$ . If the quantity of  $\text{H}_2\text{O}$  be greater, a creamy, or milky liquid remains, cream or milk of lime; a solution holding an excess in suspension. With a sufficient quantity of  $\text{H}_2\text{O}$  the hydrate is dissolved to a clear solution, which is lime water—*Liquor calcis* (U. S.; Br.). The solubility of  $\text{CaH}_2\text{O}_2$  is diminished by the presence of alkalies, and is increased by sugar or mannite; *Liq. calc. saccharatus* (Br.). Solutions of  $\text{CaH}_2\text{O}_2$  absorb  $\text{CO}_2$  with formation of a white deposit of  $\text{CaCO}_3$ .

**Calcium Chlorid**—*Calcii chloridum* (U. S.; Br.)— $\text{CaCl}_2$ —111—is obtained by dissolving marble in  $\text{HCl}$ :  $\text{CaCO}_3 + 2\text{HCl} = \text{CaCl}_2 + \text{H}_2\text{O} + \text{CO}_2$ . It is bitter; deliquescent; very soluble in  $\text{H}_2\text{O}$ ; crystallizes with 6 Aq. which it loses when fused, leaving a white, amorphous mass; used as a drying agent.

**Chloride of Lime**—*Bleaching powder*—*Calx chlorata* (U.S.; Br.)—is a white or yellowish, hygroscopic powder, prepared by passing  $\text{Cl}$  over  $\text{CaH}_2\text{O}_2$ , maintained in excess. It is bitter and acrid in taste; soluble in cold  $\text{H}_2\text{O}$ ; decomposed by boiling  $\text{H}_2\text{O}$ , and by the weakest acids, with liberation of  $\text{Cl}$ . It is decomposed by  $\text{CO}_2$ , with formation of  $\text{CaCO}_3$ , and liberation of hypochlorous acid, if it be moist; or of  $\text{Cl}$ , if it be dry. A valuable disinfectant.

Bleaching powder was formerly considered as a mixture of calcium chlorid and hypochlorite, formed by the reaction:  $2\text{CaO} + 2\text{Cl}_2 = \text{CaCl}_2 + \text{Ca}(\text{ClO})_2$ , but it is more probable that it is a definite compound having the formula  $\text{CaCl}(\text{OCl})$ , which is decomposed by  $\text{H}_2\text{O}$  into a mixture of  $\text{CaCl}_2$  and  $\text{Ca}(\text{ClO})_2$ ; and by dilute  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  with formation of  $\text{HClO}$ .

**Calcium Sulphate**— $\text{CaSO}_4$ —136—occurs in nature as *anhydrite*; and with 2 Aq in *gypsum*, *alabaster*, *selenite*; and in solution in natural waters. *Terra alba* is ground gypsum. It crystallizes with 2 Aq in right rhombic prisms; sparingly soluble in  $\text{H}_2\text{O}$ , more soluble in  $\text{H}_2\text{O}$  containing free acids or chlorids. When the hydrated salt (gypsum) is heated to 80 (176° F.), or, more rapidly, between 120–130 (248–266° F.), it loses its Aq and is converted into a white, opaque mass; which, when ground, is *plaster-of-Paris*.

The **setting** of plaster when mixed with  $\text{H}_2\text{O}$ , is due to the conversion of the anhydrous into the crystalline, hydrated salt. The ordinary plastering should never be used in hospitals, as, by reason of its irregularities and porosity, it soon becomes saturated with the transmitters of septic disease, be they germs or poisons, and cannot be thoroughly purified by disinfectants. Plaster sur-

faces may, however, be rendered dense, and be highly polished, so as to be smooth and impermeable, by adding glue and alum, or an alkaline silicate to the water used in mixing.

**Phosphates.**—Three are known:  $\text{Ca}_3(\text{PO}_4)_2$ ;  $\text{Ca}_2(\text{HPO}_4)_2$ , and  $\text{Ca}(\text{H}_2\text{PO}_4)_2$ .

**Tricalcic Phosphate**—*Tribasic or neutral phosphate*—**Bone phosphate**—**Calcii phosphas præcipitatus (U. S.)**—**Calcis phosphas (Br.)**— $\text{Ca}_3(\text{PO}_4)_2$ —310—occurs in nature, in soils, guano, *coprolites*, phosphorite, in all plants, and in every animal tissue and fluid. It is obtained by dissolving bone-ash in  $\text{HCl}$ , filtering, and precipitating with  $\text{NH}_4\text{HO}$ ; or by double decomposition between  $\text{CaCl}_2$  and an alkaline phosphate. When freshly precipitated it is gelatinous; when dry, a light, white, amorphous powder; almost insoluble in pure  $\text{H}_2\text{O}$ ; soluble to a slight extent in  $\text{H}_2\text{O}$  containing ammoniacal salts, or  $\text{NaCl}$  or  $\text{NaNO}_3$ ; readily soluble in dilute acids, even in  $\text{H}_2\text{O}$  charged with carbonic acid. It is decomposed by  $\text{H}_2\text{SO}_4$  into  $\text{CaSO}_4$  and  $\text{Ca}(\text{H}_2\text{PO}_4)_2$ . **Bone-ash** is an impure form of  $\text{Ca}_3(\text{PO}_4)_2$ , obtained by calcining bones, and used in the manufacture of P and of superphosphate.

**Dicalcic Phosphate**— $\text{Ca}_2(\text{HPO}_4)_2 + 2\text{Aq}$ —272+36—is a crystalline, insoluble salt; formed by double decomposition between  $\text{CaCl}_2$  and  $\text{HNa}_2\text{PO}_4$  in acid solution.

**Monocalcic Phosphate**—*Acid calcium phosphate*—**Superphosphate of lime**— $\text{Ca}(\text{H}_2\text{PO}_4)_2$ —234—exists in brain tissue, and in those animal liquids whose reaction is acid. It is also formed when  $\text{Ca}_3(\text{PO}_4)_2$  is dissolved in an acid, and is manufactured, for use as a manure, by decomposing bone-ash with  $\text{H}_2\text{SO}_4$ . It crystallizes in pearly plates; very soluble in  $\text{H}_2\text{O}$ . Its solutions are acid.

**Physiological.**—All three calcium phosphates, accompanied by the corresponding Mg salts, exist in the animal economy. The *tricalcic* salt occurs in all the solids of the body, and in all fluids not having an acid reaction, being held in solution in the latter by the presence of chlorids. In the fluids it is present in very small quantity, except in the milk, in which it is comparatively abundant; 2.5 to 3.95 parts per 1,000 in human milk, and 1.8 to 3.87 parts per 1,000 in cow's milk; constituting about 70 per cent. of the ash. The bones contain about 35 parts of organic matter, combined with 65 parts of mineral material. The average of human bone-ash is:  $\text{Ca}_3(\text{PO}_4)_2$ —83.89;  $\text{CaCO}_3$ —13.03; Ca, combined with Cl, F, and organic acids—0.35; F—0.23; Cl—0.18. The average quantity of  $\text{Ca}_3(\text{PO}_4)_2$  in male adult bones is 57 per cent.; that of  $\text{CaCO}_3$ , 10 per cent.; and that of  $\text{Mg}_3(\text{PO}_4)_2$ , 1.3 per cent. In pathological conditions the composition of bone is modified as shown in the following table:

* Included in tricalcic phosphate.	Frémy.	Lehmann.	Von Bibra.	Marchand.	Marchand	Ragsky.	Bequaerel and Rodier.	Bequaerel and Rodier.	Von Bibra.

The teeth consist largely of  $\text{Ca}_3(\text{PO}_4)_2$ ; the dentin of human molars containing 66.72 per cent., and the enamel 89.82 per cent.

From the urine, tricalcic phosphate is frequently deposited, either in the form of an amorphous, granular sediment, or as calculi. The *dicalcic* salt occurs occasionally in urinary sediments, in the form of needle-shaped crystals, arranged in rosettes, and also in urinary calculi. The *monocalcic* salt is always present in acid urine, constituting, with the corresponding magnesium salt, the *earthy phosphates*. The total elimination of  $\text{H}_3\text{PO}_4$  by the urine is about 2.75 grams (42.5 grains) in 24 hours; of which two-thirds are in combination with Na and K; and one-third with Ca and Mg. The hourly elimination follows about the same variation as that of the chlorids. The total elimination is greater with animal than with vegetable food; is diminished during pregnancy; and is above the normal during excessive mental work. The elimination of earthy phosphates is greatly increased in osteomalacia, often so far that they are in excess of the alkaline phosphates.

So long as the urine is *acid*, it contains the soluble acid phosphates. When the reaction becomes alkaline, or even on loss of  $\text{CO}_2$  by exposure to air, the acid phosphate is converted into the insoluble  $\text{Ca}_3(\text{PO}_4)_2$ . Alkaline urines are, for this reason, almost always turbid, and become clear on the addition of acid. It is in such urine that phosphatic calculi are invariably formed, usually about a nucleus of uric acid, or of a foreign body. If the alkalinity be due to the formation of ammonia, the trimagnesian phosphate is not formed, but ammonio-magnesian phosphate (*q. v.*).

**Quantitative determination of phosphates in urine.**—A process

for determining the quantity of phosphates in urine is based upon the formation of the insoluble uranium phosphate, and upon the production of a brown color when a solution of a uranium salt is brought in contact with a solution of potassium ferrocyanid. Four solutions are required: (1) *a standard solution of disodic phosphate*, made by dissolving 10.085 grams of crystallized, non-effloresced  $\text{HNa}_2\text{PO}_4$  in  $\text{H}_2\text{O}$ , and diluting to a litre; (2) *an acid solution of sodium acetate*, made by dissolving 100 grams sodium acetate in  $\text{H}_2\text{O}$ , adding 100 c.c. glacial acetic acid, and diluting with  $\text{H}_2\text{O}$  to a litre; (3) *a strong solution of potassium ferrocyanid*; (4) *a standard solution of uranium acetate*, made by dissolving 20.3 grams of yellow uranic oxid in glacial acetic acid, and diluting with  $\text{H}_2\text{O}$  to nearly a litre. Solution 1 serves to determine the true strength of this solution, as follows: 50 c.c. of Solution 1 are placed in a beaker, 5 c.c. of Solution 2 are added, the mixture heated on a water-bath, and the uranium solution gradually added, from a burette, until a drop from the beaker produces a brown color when brought in contact with a drop of the ferrocyanid solution. At this point the reading of the burette, which indicates the number of c.c. of the uranium solution, corresponding to  $0.1-\text{P}_2\text{O}_5$ , is taken. A quantity of  $\text{H}_2\text{O}$ , determined by calculation from the result thus obtained, is then added to the remaining uranium solution, such as to render each c.c. equivalent to 0.005 gram  $\text{P}_2\text{O}_5$ .

To determine the **total phosphates** in a urine: 50 c.c. are placed in a beaker, 5 c.c. sodium acetate solution are added; the mixture is heated on the water-bath, and the uranium solution delivered from a burette, until a drop, removed from the beaker and brought in contact with a drop of ferrocyanid solution, produces a brown tinge. The burette reading, multiplied by 0.005, gives the amount of  $\text{P}_2\text{O}_5$  in 50 c.c. urine; and this, multiplied by  $\frac{1}{50}$  the amount of urine passed in 24 hours, gives the daily elimination.

To determine the **earthy phosphates**, a sample of 100 c.c. urine is rendered alkaline with  $\text{NH}_4\text{HO}$ , and set aside for 12 hours. The precipitate is then collected upon a filter, washed with ammoniacal water, brought into a beaker, dissolved in a small quantity of acetic acid: the solution diluted to 50 c.c. with  $\text{H}_2\text{O}$ , treated with 5 c.c. sodium acetate solution, and the amount of  $\text{P}_2\text{O}_5$  determined as above.

**Calcium Carbonate**— $\text{CaCO}_3$ —100—the most abundant of the natural compounds of Ca, exists as *limestone*, *calcspar*, *chalk*, *marble*, *Iceland spar*, and *arragonite*; and forms the basis of corals, shells of crustacea and of molluses, etc.

The precipitated chalk—*Calcii carbonas præcipitata* (U. S.; Br.)—is prepared by precipitating a solution of  $\text{CaCl}_2$  with one of

$\text{Na}_2\text{CO}_3$ . **Prepared chalk—Creta præparata (U. S.; Br.)**—is native chalk, purified by grinding with  $\text{H}_2\text{O}$ , diluting, allowing the coarser particles to subside, decanting the still turbid liquid, collecting, and drying the finer particles. A process known as **elutriation**.

It is a white powder, almost insoluble in pure  $\text{H}_2\text{O}$ ; much more soluble in  $\text{H}_2\text{O}$  containing carbonic acid, the solution being regarded as containing **monocalcic carbonate**  $\text{H}_2\text{Ca}(\text{CO}_3)_2$ . At a red heat it yields  $\text{CO}_2$  and  $\text{CaO}$ . It is decomposed by acids with liberation of  $\text{CO}_2$ .

**PHYSIOLOGICAL.**—Calcium carbonate is much more abundant in the lower than in the higher forms of animal life. It occurs in the egg-shells of birds, in the bones and teeth of all animals; in solution in the saliva and urine of the herbivora, and deposited in the crystalline form, as **otoliths**, in the internal ear of man. It is deposited pathologically in calcifications, in parotid calculi, and occasionally in human urinary calculi and sediments.

**Calcium Oxalate—Oxalate of lime— $\text{CaC}_2\text{O}_4$ —128**—exists in the sap of many plants, and is formed as a white, crystalline precipitate, by double decomposition, between a Ca salt and an alkaline oxalate. It is insoluble in  $\text{H}_2\text{O}$ , acetic acid, or  $\text{NH}_4\text{HO}$ ; soluble in the mineral acids and in solution of  $\text{H}_2\text{NaPO}_4$ .

**PHYSIOLOGICAL.**—Calcium oxalate is taken into the body in vegetable food, and is formed in the economy, where its production is intimately connected with that of uric acid.

It occurs in the urine, in which it is increased in quantity when large amounts of vegetable food are taken: when sparkling wines or beers are indulged in; and when the carbonates of the alkalies, lime-water and lemon-juice, are administered. It is deposited as a urinary sediment in the form of small, brilliant octahedra, having the appearance of the backs of square letter-envelopes; or in dumb-bells. It is usually deposited from acid urine, and accompanied by crystals of uric acid. Sometimes, however, it occurs in urines undergoing alkaline fermentation, in which case it is accompanied by crystals of ammonio-magnesian phosphate.

The renal or vesical calculi of calcium oxalate, known as **mulberry calculi**, are dark brown or gray, very hard, occasionally smooth, generally tuberculated, soluble in  $\text{HCl}$  without effervescence; and when ignited, they blacken, turn white, and leave an alkaline residue. (See oxalic acid.)

**Analytical Characters.**—(1.) Ammonium sulphhydrate: nothing, unless the Ca salt be the phosphate, oxalate or fluorid, when it forms a white ppt. (2.) Alkaline carbonates: white ppt.: not prevented by the presence of ammoniacal salts. (3.) Ammonium oxalate: white ppt.: insoluble in acetic acid; soluble in  $\text{HCl}$ , or

$\text{HNO}_3$ . (4.) Sulphuric acid: white ppt., either immediately or on dilution with three volumes of alcohol; very sparingly soluble in  $\text{H}_2\text{O}$ ; insoluble in alcohol; soluble in sodium hyposulphite solution. (5.) Sodium tungstate: dense white ppt., even from dilute solutions. (6.) Colors the flame of the Bunsen burner reddish-yellow, and exhibits a spectrum of a number of bright bands, the most prominent of which are:  $\lambda = 6265, 6202, 6181, 6044, 5982, 5933, 5543$ , and  $5517$ .

### STRONTIUM.

*Symbol* = **Sr**—*Atomic weight* = 87.4—*Sp. gr.* = 2.54.

An element, not as abundant as Ba, occurring principally in the minerals *strontianite* ( $\text{SrCO}_3$ ) and *celestine* ( $\text{SrSO}_4$ ). Its compounds resemble those of Ca and Ba. Its nitrate is used in making red fire.

**Analytical characters.**—(1.) Behaves like Ba with alkaline carbonates and  $\text{Na}_2\text{HPO}_4$ . (2.) Calcium sulphate: a white ppt. which forms slowly; accelerated by addition of alcohol. (3.) The Sr compounds color the Bunsen flame red, or, as observed through blue glass, purple or rose color. The Sr flame gives a spectrum of many bands, of which the most prominent are:  $\lambda = 6694, 6664, 6059, 6031, 4607$ .

### BARIUM.

*Symbol* = **Ba**—*Atomic weight* = 136.8—*Molecular weight* = 273.6 (?)—*Sp. gr.* = 4.0—*Discovered by Davy, 1808*—*Name from basic* = heavy.

Occurs only in combination, principally as *heavy spar* ( $\text{BaSO}_4$ ) and *witherite* ( $\text{BaCO}_3$ ). It is a pale yellow, malleable metal, quickly oxidized in air, and decomposing  $\text{H}_2\text{O}$  at ordinary temperatures.

**Oxids.**—**Barium Monoxid**—**Baryta**—**BaO**—152.8—is prepared by calcining the nitrate. It is a grayish-white or white, amorphous, caustic solid. In air it absorbs moisture and  $\text{CO}_2$ , and combines with  $\text{H}_2\text{O}$  as does CaO.

**Barium Dioxid**—*Barium peroxid*—**BaO<sub>2</sub>**—168.8—is prepared by heating the monoxid in  $\text{O}$ . It is a grayish-white, amorphous solid. Heated in air it is decomposed:  $\text{BaO}_2 = \text{BaO} + \text{O}$ . Aqueous acids dissolve it with formation of a barytic salt and  $\text{H}_2\text{O}_2$ .

**Barium Monohydrate**—**BaH<sub>2</sub>O<sub>2</sub>**—170.8—is prepared by the action of  $\text{H}_2\text{O}$  on BaO. It is a white, amorphous solid, soluble in  $\text{H}_2\text{O}$ . Its aqueous solution, **baryta water**, is alkaline, and absorbs  $\text{CO}_2$ , with formation of a white deposit of  $\text{BaCO}_3$ .

**Barium Chlorid**—**BaCl<sub>2</sub> + 2Aq**—207.8+36—is obtained by treating BaS or  $\text{BaCO}_3$  with HCl. It crystallizes in prismatic plates, permanent in air, soluble in  $\text{H}_2\text{O}$ .

**Barium Nitrate**— $\text{Ba}(\text{NO}_3)_2$ —260.8—is prepared by neutralizing  $\text{HNO}_3$  with  $\text{BaCO}_3$ . It forms octahedral crystals, soluble in  $\text{H}_2\text{O}$ .

**Barium Sulphate**— $\text{BaSO}_4$ —232.8—occurs in nature as *heavy spar*, and is formed as an amorphous, white powder, insoluble in acids, by double decomposition between a Ba salt and a sulphate in solution. It is insoluble in  $\text{H}_2\text{O}$  and in acids. It is used as a pigment, **permanent white**.

**Barium Carbonate**— $\text{BaCO}_3$ —196.8—occurs in nature as *witherrite*, and is formed by double decomposition between a Ba salt and a carbonate in alkaline solution. It is a heavy, amorphous, white powder, insoluble in  $\text{H}_2\text{O}$ , soluble with effervescence in acids.

**Analytical Characters.**—(1.) Alkaline carbonates: white ppt., in alkaline solution. (2.) Sulphuric acid, or calcium sulphate: white ppt.: insoluble in acids. (3.) Sodium phosphate: white ppt.; soluble in  $\text{HNO}_3$ . (4.) Colors the Bunsen flame greenish-yellow, and exhibits a spectrum of several lines, the most prominent of which are:  $\lambda=6108, 6044, 5881, 5536$ .

**Action on the Economy.**—The oxids and hydrate act as corrosives, by virtue of their alkalinity, and also as true poisons. All soluble compounds of Ba, and those which are readily converted into soluble compounds in the stomach, are actively poisonous. Soluble sulphates, followed by emetics, are indicated as antidotes. The sulphate, notwithstanding its insolubility in water is poisonous to some animals.

#### IV. MAGNESIUM GROUP.

##### MAGNESIUM—ZINC—CADMIUM.

Each of these elements forms a single oxid—a corresponding basic hydrate, and a series of salts in which its atoms are bivalent.

##### MAGNESIUM.

*Symbol*=Mg—*Atomic weight*=24—*Molecular weight*=48 (?)—*Sp. gr.*=1.75—*Fuses at* 1000° (1832° F.)—*Discovered by Dary*, 1808.

Occurs as carbonate in *dolomite* or *magnesian limestone*, and as silicate in *mica*, *asbestos*, *soapstone*, *meerschaum*, *talc*, and in other minerals. It also accompanies Ca in the forms in which it is found in the animal and vegetable worlds.

It is prepared by heating its chlorid with Na. It is a hard, light, malleable, ductile, white metal. It burns with great brilliancy when heated in air (magnesium light), but may be distilled in H. The flash light used by photographers is a mixture of powdered Mg with an oxidizing agent,  $\text{KClO}_3$  or  $\text{KNO}_3$ . It de-

composes vapor of  $H_2O$  when heated; reduces  $CO_2$  with the aid of heat, and combines directly with Cl, S, P, As, and N. It dissolves in dilute acids, but is not affected by alkaline solutions.

**Magnesium Oxid**—**Calcined magnesia**—**Magnesia** (U. S.; Br.)— $MgO$ —40—is obtained by calcining the carbonate, hydrate, or nitrate. It is a light, bulky, tasteless, odorless, amorphous, white powder; alkaline in reaction; almost insoluble in  $H_2O$ ; readily soluble without effervescence in acids.

**Magnesium Hydrate**— $MgH_2O_2$ —58—occurs in nature, and is formed when a solution of a Mg salt is precipitated with excess of  $NaHO$ , in absence of ammoniacal salts. It is a heavy, white powder, insoluble in  $H_2O$ ; absorbs  $CO_2$ .

**Magnesium Chlorid**— $MgCl_2$ —95—is formed when  $MgO$  or  $MgCO_3$  is dissolved in  $HCl$ . It is an exceedingly deliquescent, soluble substance, which is decomposed into  $HCl$  and  $MgO$  when its aqueous solutions are evaporated to dryness. Like all the soluble Mg compounds it is bitter in taste, and accompanies the sulphate and bicarbonate in the *bitter waters*.

**Magnesium Sulphate**—**Epsom salt**—*Sedlitz salt*—**Magnesium sulphas** (U. S.)—**Magnesiæ sulphas** (Br.)— $MgSO_4 + 7 Aq$ —120 + 126—exists in solution in sea-water and in the waters of many mineral springs, especially those known as *bitter waters*. It is formed by the action of  $H_2SO_4$  on  $MgCO_3$ . It crystallizes in right rhombic prisms; bitter; slightly effervescent, and quite soluble in  $H_2O$ . Heated, it fuses and gradually loses 6 Aq up to  $132^\circ$  ( $269.6^\circ F.$ ); the last Aq it loses at  $210^\circ$  ( $410^\circ F.$ ).

**Phosphates**.—Resemble those of Ca in their constitution and properties, and accompany them in the situations in which they occur in the animal body, but in much smaller quantity.

Magnesium also forms double phosphates, constituted by the substitution of one atom of the bivalent metal for two of the atoms of basic hydrogen, of a molecule of phosphoric acid, and of an atom of an alkaline metal, or of an ammonium group, for the remaining basic hydrogen.

**Ammonio-Magnesian Phosphate**—**Triple phosphate**— $Mg(NH_4)PO_4 + 6 Aq$ —137 + 108—is produced when an alkaline phosphate and  $NH_4HO$  are added to a solution containing Mg. When heated it is converted into **magnesium pyrophosphate**  $Mg_2P_2O_7$ , in which form  $H_3PO_4$  and Mg are usually weighed in quantitative analysis.

In the urine, alkaline phosphates and magnesium salts are always present, and consequently when, by decomposition of urea, the urine becomes alkaline, the conditions for the formation of this compound are fulfilled. Being practically insoluble, especially in the presence of excess of phosphates and of ammonia, it is deposited in crystals, usually tabular, sometimes feathery and stellate in form. When it is formed in the bladder, in the pres-

ence of some body to serve as a nucleus, the crystallization takes place upon the nucleus, and a fusible calculus is produced.

**Carbonates.**—**Magnesium Carbonate**—*Neutral carbonate*— $\text{MgCO}_3$ —84—exists native in *magnesite*, and, combined with  $\text{CaCO}_3$ , in *dolomite*. It cannot be formed, like other carbonates, by decomposing a Mg salt with an alkaline carbonate, but may be obtained by passing  $\text{CO}_2$  through  $\text{H}_2\text{O}$  holding tetramagnesian tricarbo-nate in suspension.

**Trimagnesian Dicarbo-nate**— $(\text{MgCO}_3)_2\text{MgH}_2\text{O}_2+2\text{Aq}$ —226+36—is formed, in small crystals, when a solution of  $\text{MgSO}_4$  is precipitated with excess of  $\text{Na}_2\text{CO}_3$ , and the mixture boiled.

**Tetramagnesian Tricarbo-nate**—*Magnesia alba*—*Magnesium carbonas* (U. S.)—*Magnesiæ carbonas* (Br.)— $3(\text{MgCO}_3)\text{MgH}_2\text{O}_2+3\text{Aq}$ —310+54—occurs in commerce in light, white cubes, composed of a powder which is amorphous, or partly crystalline. It is prepared by precipitating a solution of  $\text{MgSO}_4$  with one of  $\text{Na}_2\text{CO}_3$ . If the precipitation occur in cold, dilute solutions (*Magnesiæ carbonas lœvis*, Br.), very little  $\text{CO}_2$  is given off; a light, bulky precipitate falls, and the solution contains magnesium, probably in the form of the bicarbonate  $\text{Mg}(\text{HCO}_3)_2$ . This solution, on standing, deposits crystals of the carbonate,  $\text{MgCO}_3+3\text{Aq}$ . If hot concentrated solutions be used, and the liquid be then boiled upon the precipitate,  $\text{CO}_2$  is given off, and a denser, heavier precipitate is formed, which varies in composition, according to the length of time during which the boiling is continued, and to the presence or absence of excess of sodium carbonate. The pharmaceutical product frequently contains  $4(\text{MgCO}_3)\text{MgH}_2\text{O}_2+4\text{H}_2\text{O}$ , or even  $2(\text{MgCO}_3)\text{MgH}_2\text{O}_2+2\text{H}_2\text{O}$ . All of these compounds are very sparingly soluble in  $\text{H}_2\text{O}$ , but much more soluble in  $\text{H}_2\text{O}$  containing ammoniacal salts.

**Analytical Characters.**—(1.) Ammonium hydrate: voluminous, white ppt. from neutral solutions. (2.) Potash or soda: voluminous, white ppt. from warm solutions: prevented by the presence of  $\text{NH}_4$  salts, and of certain organic substances. (3.) Ammonium carbonate: slight ppt. from hot solutions: prevented by the presence of  $\text{NH}_4$  salts. (4.) Sodium or potassium carbonate: white ppt., best from hot solution: prevented by the presence of  $\text{NH}_4$  compounds. (5.) Disodic phosphate: white ppt. in hot, not too dilute solutions. (6.) Oxalic acid: nothing alone, but in presence of  $\text{NH}_4\text{HO}$ , a white ppt.; not formed in presence of salts of  $\text{NH}_4$ .

## ZINC.

*Symbol* Zn—*Atomic weight* 64.9—*Molecular weight* 64.9—*Sp. gr.* = 6.862–7.215—*Fuses at* 415 (779 F.)—*Distills at* 1040 (1904 F.).

Occurs principally in *calamine* ( $\text{ZnCO}_3$ ); and *blende* ( $\text{ZnS}$ ); also as oxid and silicate; never free. It is separated from its ores by calcining, roasting, and distillation.

It is a bluish-white metal; crystalline, granular, or fibrous; quite malleable and ductile when pure. The commercial metal is usually brittle. At 130°–150° (266°–302° F.) it is pliable, and becomes brittle again above 200°–210° (392°–410° F.).

At 500° (932° F.) it burns in air, with a greenish-white flame, and gives off snowy white flakes of the oxid (*lana philosophica*; *nil album*; *pompholix*). In moist air it becomes coated with a film of hydrocarbonate. It decomposes steam when heated.

Pure  $\text{H}_2\text{SO}_4$  and pure Zn do not react together in the cold. If the acid be diluted, however, it dissolves the Zn, with evolution of  $\text{H}_2$  and formation of  $\text{ZnSO}_4$ , in the presence of a trace of Pt or Cu. The commercial metal dissolves readily in dilute  $\text{H}_2\text{SO}_4$ , with evolution of  $\text{H}_2$  and formation of  $\text{ZnSO}_4$ , the action being accelerated in presence of Pt, Cu, or As. Zinc surfaces, thoroughly coated with a layer of an amalgam of Hg and Zn, are only attacked by  $\text{H}_2\text{SO}_4$  if they form part of closed galvanic circuit; hence the zines of galvanic batteries are protected by *amalgamation*. Zinc also decomposes  $\text{HNO}_3$ ,  $\text{HCl}$ , and acetic acid.

When required for toxicological analysis, zinc must be perfectly free from As, and sometimes from P. It is better to test samples until a pure one is found, than to attempt the purification of a contaminated metal.

Zinc surfaces are readily attacked by weak organic acids. Vessels of *galvanized iron* or *sheet zinc* should therefore never be used to contain articles of food or medicines.

**Zinc Oxid**—*Zinci oxidum* (U. S.; Br.)— $\text{ZnO}$ —80.9—is prepared either by calcining the precipitated carbonate, or by burning Zn in a current of air. An impure oxid, known as *tutty*, is deposited in the flues of zinc furnaces, and in those in which brass is fused. When obtained by calcination of the carbonate, it forms a soft, white, tasteless, and odorless powder. When produced by burning the metal, it occurs in light, voluminous, white masses. It is neither fusible, volatile, nor decomposable by heat, and is completely insoluble in neutral solvents. It dissolves in dilute acids, with formation of the corresponding salts.

It is used in the arts as a white pigment in place of lead carbonate, and is not darkened by  $\text{H}_2\text{S}$ .

**Zinc Hydrate**— $\text{ZnH}_2\text{O}_2$ —98.9—is not formed by union of  $\text{ZnO}$  and  $\text{H}_2\text{O}$ ; but is produced when a solution of a Zn salt is treated with  $\text{KHO}$ . Freshly prepared, it is very soluble in alkalies, and in solutions of  $\text{NH}_4$  salts.

**Zinc Chlorid**—**Butter of zinc**—**Zinci chloridum** (**U. S.**; **Br.**)— $\text{ZnCl}_2 + \text{Aq}$ —135.9+18—is obtained by dissolving Zn in  $\text{HCl}$ ; or by heating Zn in  $\text{Cl}$ . It is a soft, white, very deliquescent, fusible, volatile mass; very soluble in  $\text{H}_2\text{O}$ , somewhat less so in alcohol. Its solution has a burning metallic taste; destroys vegetable tissues; dissolves silk; and exerts a strong dehydrating action upon organic substances in general.

In dilute solution it is used as a disinfectant and antiseptic (*Burnett's fluid*), as a preservative of wood and as an embalming injection.

**Zinc Sulphate**—**White vitriol**—**Zinci sulphas** (**U. S.**; **Br.**)— $\text{ZnSO}_4 + n\text{Aq}$ —160.9+ $n$ 18—is formed when Zn,  $\text{ZnO}$ ,  $\text{ZnS}$ , or  $\text{ZnCO}_3$  is dissolved in diluted  $\text{H}_2\text{SO}_4$ . It crystallizes below 30° (86° F.) with 7 Aq; at 30° (86° F.) with 6 Aq; between 40°–50° (104°–122° F.) with 5 Aq; at 0° (32° F.) from concentrated acid solution with 4 Aq. From a boiling solution it is precipitated by concentrated  $\text{H}_2\text{SO}_4$  with 2Aq; from a saturated solution at 100° (212° F.) with 1 Aq; and anhydrous, when the salt with 1 Aq is heated to 238° (460° F.).

The salt usually met with is that with 7 Aq, which is in large, colorless, four-sided prisms; efflorescent; very soluble in  $\text{H}_2\text{O}$ ; sparingly soluble in weak alcohol. Its solutions have a strong, styptic taste; coagulate albumin when added in moderate quantity, the coagulum dissolving in an excess; and form insoluble precipitates with the tannins.

**Carbonates.**—**Zinc Carbonate**— $\text{ZnCO}_3$ —124.9—occurs in nature as *calamine*. If an alkaline carbonate be added to a solution of a Zn salt, the neutral carbonate, as in the case of Mg, is not formed, but an oxycarbonate,  $n\text{ZnCO}_3, n\text{ZnH}_2\text{O}_2$  [**Zinci carbonas** (**U. S.**; **Br.**)], whose composition varies with the conditions under which it is formed.

**Analytical Characters**—(1.) Hydrate of K, Na or  $\text{NH}_4$ : white ppt., soluble in excess. (2.) Carbonate of K or Na; white ppt., in absence of  $\text{NH}_4$  salts. (3.) Hydrogen sulphid, in neutral solution: white ppt. In presence of an excess of a mineral acid, the formation of this ppt. is prevented, unless sodium acetate be also present. (4.) Ammonium sulphhydrate: white ppt., insoluble in excess, in  $\text{KHO}$ ,  $\text{NH}_4\text{HO}$ , or acetic acid; soluble in dilute mineral acids. (5.) Ammonium carbonate: white ppt., soluble in excess. (6.) Disodic phosphate, in absence of  $\text{NH}_4$  salts: white ppt., soluble in acids or alkalies. (7.) Potassium ferrocyanid: white ppt., insoluble in  $\text{HCl}$ .

**Action on the Economy.**—All the compounds of Zn which are

soluble in the digestive fluids behave as true poisons; and solutions of the chlorid (in common use by tinsmiths, and in disinfecting fluids) have also well-marked corrosive properties. When Zn compounds are taken, it is almost invariably by mistake for other substances: the sulphate for Epsom salt, and solutions of the chlorid for various liquids, gin, fluid magnesia, vinegar, etc.

Metallie zinc is dissolved by solutions containing NaCl, or organic acids, for which reason articles of food kept in vessels of galvanized iron become contaminated with zinc compounds, and, if eaten, produce more or less intense symptoms of intoxication. For the same reason materials intended for analysis, in cases of supposed poisoning, *should never be packed in jars closed by zinc caps.*

### CADMIUM.

*Symbol*=Cd—*Atomic weight*=111.8—*Molecular weight*=111.8—*Sp. gr.*=8.604—*Fuses at* 227°.8 (442° F.)—*Boils at* 860° (1580° F.).

A white metal, malleable and ductile at low temperature, brittle when heated; which accompanies Zn in certain of its ores. It resembles zinc in its physical as well as its chemical characters. It is used in certain fusible alloys, and its iodid is used in photography.

**Analytical Characters.**—Hydrogen sulphid: bright yellow ppt.: insoluble in  $\text{NH}_4\text{HS}$ , and in dilute acids and alkalies, soluble in boiling  $\text{HNO}_3$  or  $\text{HCl}$ .

## V. NICKEL GROUP.

### NICKEL—COBALT.

These two elements bear some resemblance chemically to those of the Fe group; from which they differ in forming, so far as known, no compounds similar to the ferrates, chromates, and manganates, unless the barium cobaltite, recently described by Rousseau, be such. They form compounds corresponding to  $\text{Fe}_2\text{O}_3$ , but those corresponding to the ferric series are either wanting or exceedingly unstable.

### NICKEL.

*Symbol*=Ni—*Atomic weight*=58—*Sp. gr.*=8.637.

Occurs in combination with S, and with S and As.

It is a white metal, hard, slightly magnetic, not tarnished in air. *German silver* is an alloy of Ni, Cu, and Zn. Nickel is now extensively used for plating upon other metals, and for the man-

ufacture of dishes, etc., for use in the laboratory. Its salts are green.

**Analytical Characters.**—(1.) Ammonium sulphhydrate: black ppt.; insoluble in excess. (2.) Potash or soda: apple-green ppt., in absence of tartaric acid; insoluble in excess. (3.) Ammonium hydrate: apple-green ppt.; soluble in excess; forming a violet solution, which deposits the apple-green hydrate, when heated with KHO:

### COBALT.

*Symbol*=Co—*Atomic weight*=58.9—*Sp. gr.*=8.5–8.7.

Occurs in combination with As and S. Its salts are red when hydrated, and usually blue when anhydrous. Its phosphate is used as a blue pigment.

**Analytical Characters.**—(1.) Ammonium sulphhydrate: black ppt.; insoluble in excess. (2.) Potash: blue ppt.; turns red, slowly in the cold, quickly when heated; not formed in the cold in the presence of  $\text{NH}_4$  salts. (3.) Ammonium hydrate: blue ppt.; turns red in absence of air, green in its presence.

## VI. COPPER GROUP.

### COPPER—MERCURY.

Each of these elements forms two series of compounds. One contains compounds of the bivalent group  $\left( \begin{smallmatrix} \text{Cu} \\ | \\ \text{Cu} \end{smallmatrix} \right)^{''}$  or  $(\text{Hg}_2)^{''}$ , which are designated by the termination *ous*; the other contains compounds of single, bivalent atoms  $\text{Cu}^{''}$  or  $\text{Hg}^{''}$ , which are designated by the termination *ic*.

### COPPER.

*Symbol* = Cu (**CUPRUM**)—*Atomic weight* = 63.1—*Molecular weight*=127 (?)—*Sp. gr.*=8.914–8.952—*Fuses at* 1091 (1996° F.).

**Occurrence.**—It is found free, in crystals or amorphous masses, sometimes of great size; also a sulphid, *copper pyrites*; oxid, *ruby ore* and *black oxid*; and basic carbonate, *malachite*.

**Properties.**—*Physical.*—A yellowish-red metal; dark brown when finely divided; very malleable, ductile, and tenacious; a good conductor of heat and electricity; has a peculiar, metallic taste and a characteristic odor.

*Chemical.*—It is unaltered in dry air at the ordinary temperature; but, when heated to redness, is oxidized to  $\text{CuO}$ . In damp

air it becomes coated with a brownish film of oxid; a green film of basic carbonate; or, in salt air, a green film of basic chlorid. Hot  $\text{H}_2\text{SO}_4$  dissolves it with formation of  $\text{CuSO}_4$  and  $\text{SO}_2$ . It is dissolved by  $\text{HNO}_3$  with formation of  $\text{Cu}(\text{NO}_3)_2$  and  $\text{NO}$ ; and by  $\text{HCl}$  with liberation of  $\text{H}$ . Weak acids form with it soluble salts, in presence of air and moisture. It is dissolved by  $\text{NH}_4\text{HO}$ , in presence of air, with formation of a blue solution. It combines directly with  $\text{Cl}$ , frequently with light.

**Oxids.**—**Cuprous Oxid**—*Suboxid or red oxid of copper*— $(\text{Cu}_2)\text{O}$ —142.4—is formed by calcining a mixture of  $(\text{Cu}_2)\text{Cl}_2$  and  $\text{Na}_2\text{CO}_3$ ; or a mixture of  $\text{CuO}$  and  $\text{Cu}$ . It is a red or yellow powder; permanent in air; sp. gr. 5.749–6.093; fuses at a red heat; easily reduced by  $\text{C}$  or  $\text{H}$ . Heated in air it is converted into  $\text{CuO}$ .

**Cupric Oxid**—*Binoxid or black oxid of copper*— $\text{CuO}$ —79.2—is prepared by heating  $\text{Cu}$  to dull redness in air; or by calcining  $\text{Cu}(\text{NO}_3)_2$ ; or by prolonged boiling of the liquid over a precipitate, produced by heating a solution of a cupric salt, in presence of glucose, with  $\text{KHO}$ . By the last method it is sometimes produced in Trommer's test for glucose, when an excessive quantity of  $\text{CuSO}_4$  has been used.

It is a black, or dark reddish-brown, amorphous solid; readily reduced by  $\text{C}$ ,  $\text{H}$ ,  $\text{Na}$ , or  $\text{K}$  at comparatively low temperatures. When heated with organic substances, it gives up its  $\text{O}$ , converting the  $\text{C}$  into  $\text{CO}_2$ , and the  $\text{H}$  into  $\text{H}_2\text{O}$ :  $\text{C}_2\text{H}_6\text{O} + 6\text{CuO} = 6\text{Cu} + 2\text{CO}_2 + 3\text{H}_2\text{O}$ ; a property which renders it valuable in organic analysis, as by heating a known weight of organic substance with  $\text{CuO}$ , and weighing the amount of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  produced, the percentage of  $\text{C}$  and  $\text{H}$  may be obtained. It dissolves in acids with formation of salts.

**Hydrates.**—**Cuprous Hydrate**— $(\text{Cu}_2)\text{H}_2\text{O}_2$  (?)—160.4 (?)—is formed as a yellow or red powder when mixed solutions of  $\text{CuSO}_4$  and  $\text{KHO}$  are heated in presence of glucose. By boiling the solution it is rapidly dehydrated with formation of  $(\text{Cu}_2)\text{O}$ .

**Cupric Hydrate**— $\text{CuH}_2\text{O}_2$ —97.2—is formed by the action of  $\text{KHO}$  upon solution of  $\text{CuSO}_4$ , in absence of reducing agents and in the cold. It is a bluish, amorphous powder; very unstable, and readily dehydrated, with formation of  $\text{CuO}$ .

**Sulphids.**—**Cuprous Sulphid**—*Subsulphid or protosulphid of copper*— $\text{Cu}_2\text{S}$ —158.4—occurs in nature as *copper glance* or *chalcocine*, and in many double sulphids, *pyrites*.

**Cupric Sulphid**— $\text{CuS}$ —95.2—is formed by the action of  $\text{H}_2\text{S}$ , or of  $\text{NH}_4\text{HS}$ , on solutions of cupric salts. It is almost black when moist, greenish-brown when dry. Hot  $\text{HNO}_3$  oxidizes it to  $\text{CuSO}_4$ ; hot  $\text{HCl}$  converts it into  $\text{CuCl}_2$ , with separation of  $\text{S}$ , and formation of  $\text{H}_2\text{S}$ . It is sparingly soluble in  $\text{NH}_4\text{HS}$ , its solubility being increased by the presence of organic matter.

**Chlorids.**—**Cuprous Chlorid**—*Subchlorid or protochlorid*—( $\text{Cu}_2$ ) $\text{Cl}_2$ —197.4—is prepared by heating Cu with one of the chlorids of Hg; by dissolving ( $\text{Cu}_2$ )O in HCl, without contact of air; or by the action of reducing agents on solutions of  $\text{CuCl}_2$ . It is a heavy, white powder; turns violet and blue by exposure to light; soluble in HCl; insoluble in  $\text{H}_2\text{O}$ . It forms a crystallizable compound with CO; and its solution in HCl is used in analysis to absorb that gas.

**Cupric Chlorid**—*Chlorid or deutochlorid*— $\text{CuCl}_2$ —134.2—is formed by dissolving Cu in aqua regia. If the Cu be in excess, it reduces  $\text{CuCl}_2$  to ( $\text{Cu}_2$ ) $\text{Cl}_2$ . It crystallizes in bluish-green, rhombic prisms with 2 Aq; deliquescent; very soluble in  $\text{H}_2\text{O}$  and in alcohol.

**Cupric Nitrate**— $\text{Cu}(\text{NO}_3)_2$ —187.2—is formed by dissolving Cu, CuO, or  $\text{CuCO}_3$  in  $\text{HNO}_3$ . It crystallizes at 20–25° (68–77° F.) with 3 Aq; below 20° (68° F.) with 6 Aq, forming blue, deliquescent needles. Strongly heated, it is converted into CuO.

**Cupric Sulphate**—**Blue vitriol**—**Blue stone**—**Cupri sulphas** (U. S.; Br.)— $\text{CuSO}_4 + 5\text{Aq}$ —159.2+90—is prepared: (1) by roasting Cu S; (2) from the water of copper mines; (3) by exposing Cu, moistened with dilute  $\text{H}_2\text{SO}_4$ , to air; (4) by heating Cu with  $\text{H}_2\text{SO}_4$ .

As ordinarily crystallized, it is in fine, blue, oblique prisms; soluble in  $\text{H}_2\text{O}$ ; insoluble in alcohol; efflorescent in dry air at 15° (59° F.), losing 2 Aq. At 100° (212° F.) it still retains 1 Aq, which it loses at 230° (446° F.), leaving a white, amorphous powder of the anhydrous salt, which, on taking up  $\text{H}_2\text{O}$ , resumes its blue color. Its solutions are blue, acid, styptic, and metallic in taste.

When  $\text{NH}_4\text{HO}$  is added to a solution of  $\text{CuSO}_4$ , a bluish-white precipitate falls, which redissolves in excess of the alkali, to form a deep blue solution. Strong alcohol floated over the surface of this solution separates long, right rhombic prisms, having the composition  $\text{CuSO}_4 \cdot 4\text{NH}_3 + \text{H}_2\text{O}$ , which are very soluble in  $\text{H}_2\text{O}$ . This solution constitutes ammonio-sulphate of copper or aqua sapphirina.

**Arsenite**—**Scheele's green**—**Mineral green**—is a mixture of cupric arsenite and hydrate: prepared by adding potassium arsenite to solution of  $\text{CuSO}_4$ . It is a grass-green powder, insoluble in  $\text{H}_2\text{O}$ ; soluble in  $\text{NH}_4\text{HO}$ , or in acids. Exceedingly poisonous.

**Schweinfurt Green**—**Mitis green** or **Paris green**—is the most frequently used, and the most dangerous of the cupro-arsenical pigments. It is prepared by adding a thin paste of neutral cupric acetate with  $\text{H}_2\text{O}$  to a boiling solution of arsenious acid, and continuing the boiling during a further addition of acetic acid. It is an insoluble, green, crystalline powder, having the composition  $(\text{C}_2\text{H}_3\text{O}_2)_2\text{Cu} + 3(\text{As}_2\text{O}_3 \cdot \text{Cu})$ . It is decomposed by prolonged boiling in  $\text{H}_2\text{O}$ , by aqueous solutions of the alkalies, and by the mineral acids.

**Carbonates.**—The existence of cuprous carbonate is doubtful. **Cupric carbonate**— $\text{CuCO}_3$ —exists in nature, but has not been obtained artificially. **Dicupric carbonate**— $\text{CuCO}_3, \text{CuH}_2\text{O}_2$ —exists in nature as malachite. When a solution of a cupric salt is decomposed by an alkaline carbonate, a bluish precipitate, having the composition  $\text{CuCO}_3, \text{CuH}_2\text{O}_2 \frac{1}{2} \text{H}_2\text{O}$ , is formed, which, on drying, loses  $\text{H}_2\text{O}$ , and becomes green; it is used as a pigment under the name mineral green. **Tricupric carbonate**—*Sesquicarbonate of copper*— $2(\text{CuCO}_3), \text{CuH}_2\text{O}_2$ —exists in nature as a blue mineral, called azurite or mountain blue, and is prepared by a secret process for use as a pigment known as blue ash.

**Acetates.**—**Cupric Acetate**—*Diacetate*—*Crystals of Venus*—**Cupri acetat** (U. S.)— $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 + \text{Aq}$ —181.2+18—is formed when  $\text{CuO}$  or verdigris is dissolved in acetic acid; or by decomposition of a solution of  $\text{CuSO}_4$  by  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ . It crystallizes in large, bluish-green prisms, which lose their  $\text{Aq}$  at  $140^\circ$  ( $284^\circ \text{F.}$ ). At  $240^\circ$ – $260^\circ$  ( $464^\circ$ – $500^\circ \text{F.}$ ) they are decomposed with liberation of glacial acetic acid.

**Basic Acetates.**—**Verdigris**—is a substance prepared by exposing to air piles composed of alternate layers of grape-skins and plates of copper, and removing the bluish-green coating from the copper. It is a mixture, in varying proportions, of three different substances:  $(\text{C}_2\text{H}_3\text{O}_2)_2\text{CuH}_2\text{O}_2 + 5\text{Aq}$ ;  $[(\text{C}_2\text{H}_3\text{O}_2)_2\text{Cu}]_2, \text{CuH}_2\text{O}_2 + 5\text{Aq}$ ; and  $(\text{C}_2\text{H}_3\text{O}_2)_2\text{Cu}, 2(\text{CuH}_2\text{O}_2)$ .

**Analytical Characters.**—**CUPROUS**—are very unstable and readily converted into cupric compounds. (1.) Potash: white ppt.; turning brownish. (2.) Ammonium hydrate, in absence of air: a colorless liquid; turns blue in air.

**CUPRIC**—are white when anhydrous; when soluble in  $\text{H}_2\text{O}$  they form blue or green, acid solutions. (1.) Hydrogen sulphid: black ppt.; insoluble in  $\text{KHS}$  or  $\text{NaHS}$ ; sparingly soluble in  $\text{NH}_4\text{HS}$ ; soluble in hot concentrated  $\text{HNO}_3$  and in  $\text{KCN}$ . (2.) Alkaline sulphhydrates: same as  $\text{H}_2\text{S}$ . (3.) Potash or soda: pale blue ppt.; insoluble in excess. If the solution be heated over the ppt., the latter contracts and turns black. (4.) Ammonium hydrate, in small quantity: pale blue ppt.; in larger quantity, deep blue solution. (5.) Potassium or sodium carbonate: greenish-blue ppt.; insoluble in excess; turning black when the liquid is boiled. (6.) Ammonium carbonate: pale blue ppt.; soluble with deep blue color in excess. (7.) Potassium cyanid: greenish-yellow ppt.; soluble in excess. (8.) Potassium ferrocyanid: chestnut-brown ppt.; insoluble in weak acids; decolorized by  $\text{KHO}$ . (9.) Iron is coated with metallic  $\text{Cu}$ .

**Action on the Economy.**—The opinion, until recently universal

among toxicologists, that all the compounds of copper are poisonous, has been much modified by recent researches. Certain of the copper compounds, such as the sulphate, having a tendency to combine with albuminoid and other animal substances, produce symptoms of irritation by their direct local action, when brought in contact with the gastric or intestinal mucous membrane. One of the characteristic symptoms of such irritation is the vomiting of a greenish matter, which develops a blue color upon the addition of  $\text{NH}_4\text{HO}$ .

Cases are not wanting in which severe illness, and even death, has followed the use of food which has been in contact with imperfectly tinned copper vessels. Cases in which nervous and other symptoms referable to a truly poisonous action have occurred. As, however, it has also been shown that non-irritant, *pure* copper compounds may be taken in considerable doses with impunity, it appears at least probable that the poisonous action attributed to copper is due to other substances. The tin and solder used in the manufacture of copper utensils contain lead, and in some cases of so-called copper-poisoning, the symptoms have been such as are as consistent with lead-poisoning as with copper-poisoning. Copper is also notoriously liable to contamination with arsenic, and it is by no means improbable that compounds of that element are the active poisonous agents in some cases of supposed copper-intoxication. Nor is it improbable that articles of food allowed to remain exposed to air in copper vessels should undergo those peculiar changes which result in the formation of poisonous substances, such as the sausage- or cheese-poisons, or the ptomaines.

The treatment, when irritant copper compounds have been taken, should consist in the administration of white of egg or of milk, with whose albuminoids an inert compound is formed by the copper salt. If vomiting do not occur spontaneously, it should be induced by the usual methods.

The detection of copper in the viscera after death is not without interest, especially if arsenic have been found, in which case its discovery or non-discovery enables us to differentiate between poisoning by the arsenical greens, and that by other arsenical compounds. The detection of mere traces of copper is of no significance, because, although copper is not a physiological constituent of the body, it is almost invariably present, having been taken with the food.

Pickles and canned vegetables are sometimes intentionally *greened* by the addition of copper; this fraud is readily detected by inserting a large needle into the pickle or other vegetable: if copper be present the steel will be found to be coated with copper after half an hour's contact.

## MERCURY.

*Symbol*=**Hg** (**HYDRARGYRUM**)—*Atomic weight*=199.7—*Molecular weight*=199.7—*Sp. gr. of liquid*=13.596; *of vapor*=6.97—*Fuses at*  $-38.8$  ( $-37.9$  F.)—*Boils at*  $350^{\circ}$  ( $662^{\circ}$  F.).

**Occurrence.**—Chiefly as *cinnabar* ( $\text{HgS}$ ); also in small quantity free and as chlorid.

**Preparation.**—The commercial product is usually obtained by simple distillation in a current of air:  $\text{HgS} + \text{O}_2 = \text{Hg} + \text{SO}_2$ . If required pure, it must be freed from other metals by distillation, and agitation of the redistilled product with mercurous nitrate solution, solution of  $\text{Fe}_2\text{Cl}_6$ , or dilute  $\text{HNO}_3$ .

**Properties.**—*Physical.*—A bright metallic liquid; volatile at all temperatures. Crystallizes in octahedra of sp. gr. 14.0. When pure, it rolls over a smooth surface in round drops. The formation of tear-shaped drops indicates the presence of impurities.

*Chemical.*—If pure, it is not altered by air at the ordinary temperature, but, if contaminated with foreign metals, its surface becomes dimmed. Heated in air, it is oxidized superficially to  $\text{HgO}$ . It does not decompose  $\text{H}_2\text{O}$ . It combines directly with Cl, Br, I and S. It alloys readily with most metals to form amalgams. It amalgamates with Fe and Pt only with difficulty. Hot, concentrated  $\text{H}_2\text{SO}_4$  dissolves it, with evolution of  $\text{SO}_2$ , and formation of  $\text{HgSO}_4$ . It dissolves in cold  $\text{HNO}_3$ , with formation of a nitrate.

Elementary mercury is insoluble in  $\text{H}_2\text{O}$ , and probably in the digestive liquids. It enters, however, into the formation of three medicinal agents: *hydrargyrum cum creta* (**U.S.**; **Br.**); *massa hydrargyri* (**U.S.**)=*pilula hydrargyri* (**Br.**); and *unguentum hydrargyri* (**U.S.**; **Br.**), all of which owe their efficacy, not to the metal itself, but to a certain proportion of oxid, produced during their manufacture. The fact that blue mass is more active than mercury with chalk is due to the greater proportion of oxid contained in the former. It is also probable that absorption of vapor of Hg by cutaneous surfaces is attended by its conversion into  $\text{HgCl}_2$ .

**Oxids.**—**Mercurous Oxid**—*Protoxid or black oxid of mercury*— $(\text{Hg}_2)\text{O}$ —415.4—is obtained by adding a solution of  $(\text{Hg}_2)(\text{NO}_3)_2$  to an excess of solution of  $\text{KHO}$ . It is a brownish-black, tasteless powder; very prone to decomposition into  $\text{HgO}$  and Hg. It is converted into  $(\text{Hg}_2)\text{Cl}_2$  by  $\text{HCl}$ ; and by other acids into the corresponding mercurous salts.

It is formed by the action of  $\text{CaH}_2\text{O}_2$  on mercurous compounds, and exists in **black wash**.

**Mercuric Oxid**—*Red, or binoxid of mercury*—**Hydrargyri oxidum flavum (U. S.; Br.)**—**Hydrargyri oxidum rubrum (U. S.; Br.)**—**HgO**—215.7—is prepared by two methods: (1) by calcining  $\text{Hg}(\text{NO}_3)_2$ , as long as brown fumes are given off (*Hydr. oxid. rubr.*); or, (2) by precipitating a solution of a mercuric salt by excess of  $\text{KHO}$  (*Hydr. oxid. flavum*). The products obtained, although the same in composition, differ in physical characters and in the activity of their chemical actions. That obtained by (1) is red and crystalline; that obtained by (2) is yellow and amorphous. The latter is much the more active in its chemical and medicinal actions.

It is very sparingly soluble in  $\text{H}_2\text{O}$ , the solution having an alkaline reaction, and a metallic taste. It exists both in solution and in suspension in **yellow wash**, prepared by the action of  $\text{CaH}_2\text{O}_2$  on a mercuric compound.

Exposed to light and air, it turns black, more rapidly in presence of organic matter, giving off  $\text{O}$ , and liberating  $\text{Hg}$ :  $\text{HgO} = \text{Hg} + \text{O}$ . It decomposes the chlorids of many metallic elements in solution, with formation of a metallic oxid and mercuric oxychlorids. It combines with alkaline chlorids to form soluble double chlorids, called **chloromercurates** or **chlorhydrargyrates**; and forms similar compounds with alkaline iodids and bromids.

**Sulphids.**—**Mercurous Sulphid**—**(Hg<sub>2</sub>)S**—431.4—a very unstable compound, formed by the action of  $\text{H}_2\text{S}$  on mercurous salts.

**Mercuric Sulphid**—*Red sulphid of mercury*—**Cinnabar**—**Vermilion**—**Hydrargyri sulphidum rubrum (U. S.)**—**HgS**—231.7—exists in nature in amorphous red masses, or in red crystals, and is the chief ore of  $\text{Hg}$ . If  $\text{Hg}$  and  $\text{S}$  be ground up together in the cold, or if a solution of a mercuric salt be completely decomposed by  $\text{H}_2\text{S}$ , a black sulphid is obtained, which is the **Æthiops mineralis** of the older pharmacists.

A red sulphid is obtained for use as a pigment (**vermilion**), by agitating for some hours at  $60^\circ$  ( $140^\circ \text{F.}$ ) a mixture of  $\text{Hg}$ ,  $\text{S}$ ,  $\text{KHO}$ , and  $\text{H}_2\text{O}$ . It is a fine, red powder, which turns brown, and finally black, when heated. Heated in air, it burns to  $\text{SO}_2$  and  $\text{Hg}$ . It is decomposed by strong  $\text{H}_2\text{SO}_4$ , but not by  $\text{HNO}_3$  or  $\text{HCl}$ .

**Chlorids.**—**Mercurous Chlorid**—*Protochlorid or mild chlorid of mercury*—**Calomel**—**Hydrargyri chloridum mite (U. S.)**—**Hydrargyri subchloridum (Br.)**—**(Hg<sub>2</sub>)Cl<sub>2</sub>**—470.4—is now principally obtained by mutual decomposition of  $\text{NaCl}$  and  $(\text{Hg}_2)\text{SO}_4$ . Mercuric sulphate is first obtained by heating together 2 pts.  $\text{Hg}$  and 3 pts.  $\text{H}_2\text{SO}_4$ ; the product is then caused to combine with a quantity of  $\text{Hg}$  equal to that first used, to form  $(\text{Hg}_2)\text{SO}_4$ ; which is then mixed with dry  $\text{NaCl}$ , and the mixture heated in glass vessels, connected with condensing chambers;  $2\text{NaCl} + (\text{Hg}_2)\text{SO}_4 = \text{Na}_2\text{SO}_4 + (\text{Hg}_2)\text{Cl}_2$ .

In practice, varying quantities of  $\text{HgCl}_2$  are also formed, and must be removed from the product by washing with boiled, distilled  $\text{H}_2\text{O}$ , until the washings no longer precipitate with  $\text{NH}_4\text{HO}$ . The presence of  $\text{HgCl}_2$  in calomel may be detected by the formation of a black stain upon a bright copper surface, immersed in the calomel, moistened with alcohol; or by the production of a black color by  $\text{H}_2\text{S}$  in  $\text{H}_2\text{O}$  which has been in contact with and filtered from calomel so contaminated.

Calomel is also formed in a number of other reactions: (1) by the action of  $\text{Cl}$  upon excess of  $\text{Hg}$ ; (2) by the action of  $\text{Hg}$  upon  $\text{Fe}_2\text{Cl}_6$ ; (3) by the action of  $\text{HCl}$ , or of a chlorid, upon  $(\text{Hg}_2)\text{O}$ , or upon a mercurous salt; (4) by the action of reducing agents, including  $\text{Hg}$ , upon  $\text{HgCl}_2$ .

Calomel crystallizes in nature, and when sublimed, in quadratic prisms. When precipitated it is deposited as a heavy, amorphous, white powder, faintly yellowish, and producing a yellowish mark when rubbed upon a dark surface. It sublimes, without fusing, between  $420^\circ$  and  $500^\circ$  ( $788$ – $932^\circ \text{F.}$ ), is insoluble in cold  $\text{H}_2\text{O}$  and in alcohol; soluble in boiling  $\text{H}_2\text{O}$  to the extent of 1 part in 12,000. When boiled with  $\text{H}_2\text{O}$  for some time, it suffers partial decomposition,  $\text{Hg}$  is deposited and  $\text{HgCl}_2$  dissolves.

Although  $\text{Hg}_2\text{Cl}_2$  is insoluble in  $\text{H}_2\text{O}$ , in dilute  $\text{HCl}$ , and in pepsin solution, it is dissolved at the body temperature in an aqueous solution of pepsin acidulated with  $\text{HCl}$ .

When exposed to light, calomel becomes yellow, then gray, owing to partial decomposition, with liberation of  $\text{Hg}$  and formation of  $\text{HgCl}_2$ :  $(\text{Hg}_2)\text{Cl}_2 = \text{Hg} + \text{HgCl}_2$ . It is converted into  $\text{HgCl}_2$  by  $\text{Cl}$  or aqua regia:  $(\text{Hg}_2)\text{Cl}_2 + \text{Cl}_2 = 2\text{HgCl}_2$ . In the presence of  $\text{H}_2\text{O}$ ,  $\text{I}$  converts it into a mixture of  $\text{HgCl}_2$  and  $\text{HgI}_2$ :  $(\text{Hg}_2)\text{Cl}_2 + \text{I}_2 = \text{HgCl}_2 + \text{HgI}_2$ . It is also converted into  $\text{HgCl}_2$  by  $\text{HCl}$  and by alkaline chlorids:  $(\text{Hg}_2)\text{Cl}_2 = \text{HgCl}_2 + \text{Hg}$ . This change occurs in the stomach when calomel is taken internally, and that to such an extent when large quantities of  $\text{NaCl}$  is taken with the food, that calomel cannot be used in naval practice as it may be with patients who do not subsist upon salt provisions. It is converted by  $\text{KI}$  into  $(\text{Hg}_2)\text{I}_2$ :  $(\text{Hg}_2)\text{Cl}_2 + 2\text{KI} = 2\text{KCl} + (\text{Hg}_2)\text{I}_2$ ; which is then decomposed by excess of  $\text{KI}$  into  $\text{Hg}$  and  $\text{HgI}_2$ , the latter dissolving:  $(\text{Hg}_2)\text{I}_2 = \text{Hg} + \text{HgI}_2$ . Solutions of the sulphates of  $\text{Na}$ ,  $\text{K}$ , and  $\text{NH}_4$  dissolve notable quantities of  $(\text{Hg}_2)\text{Cl}_2$ . The hydrates and carbonates of  $\text{K}$  and  $\text{Na}$  decompose it with formation of  $(\text{Hg}_2)\text{O}$ :  $(\text{Hg}_2)\text{Cl}_2 + \text{Na}_2\text{CO}_3 = (\text{Hg}_2)\text{O} + \text{CO}_2 + 2\text{NaCl}$ ; and the  $(\text{Hg}_2)\text{O}$  so formed is decomposed into  $\text{HgO}$  and  $\text{Hg}$ . If alkaline chlorids be also present, they react upon the  $\text{HgO}$  so produced, with formation of  $\text{HgCl}_2$ .

**Mercuric Chlorid**—*Perchlorid or bichlorid of mercury*—Corrosive sublimate—*Hydrargyri chloridum corrosivum* (U. S.)—**Hy-**

**drargyri perchloridum (Br.)**— $\text{HgCl}_2$ —270.7—is prepared by heating a mixture of 5 pts. dry  $\text{HgSO}_4$  with 5 pts. dry  $\text{NaCl}$ , and 1 pt.  $\text{MnO}_2$  in a glass vessel communicating with a condensing chamber.

It crystallizes by sublimation in octahedra, and by evaporation of its solutions in flattened, right rhombic prisms; fuses at 265° (509° F.), and boils at about 295° (563° F.); soluble in  $\text{H}_2\text{O}$  and in alcohol; very soluble in hot  $\text{HCl}$ , the solution gelatinizing on cooling. Its solutions have a disagreeable, acid, styptic taste, and are highly poisonous.

It is easily reduced to  $(\text{Hg}_2)\text{Cl}_2$  and  $\text{Hg}$ , and its aqueous solutions are so decomposed when exposed to light; a change which is retarded by the presence of  $\text{NaCl}$ . Heated with  $\text{Hg}$ , it is converted into  $(\text{Hg}_2)\text{Cl}_2$ . When dry  $\text{HgCl}_2$ , or its solution, is heated with  $\text{Zn}$ ,  $\text{Cd}$ ,  $\text{Ni}$ ,  $\text{Fe}$ ,  $\text{Pb}$ ,  $\text{Cu}$ , or  $\text{Bi}$ , those elements remove part or all of its  $\text{Cl}$ , with separation of  $(\text{Hg}_2)\text{Cl}_2$  or  $\text{Hg}$ . Its solution is decomposed by  $\text{H}_2\text{S}$ , with separation of a yellow sulphochlorid, which, with an excess of the gas, is converted into black  $\text{HgS}$ . It is soluble without decomposition in  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , and  $\text{HCl}$ . It is decomposed by  $\text{KHO}$  or  $\text{NaHO}$ , with separation of a brown oxychlorid if the alkaline hydrate be in limited quantity; or of the orange-colored  $\text{HgO}$  if it be in excess. A similar decomposition is effected by  $\text{CaH}_2\text{O}_2$  and  $\text{MgH}_2\text{O}_2$ ; which does not, however, take place in presence of an alkaline chlorid, or of certain organic matters, such as sugar and gum. Many organic substances decompose it into  $(\text{Hg}_2)\text{Cl}_2$  and  $\text{Hg}$ , especially under the influence of sunlight. Albumen forms with it a white precipitate, which is insoluble in  $\text{H}_2\text{O}$ , but soluble in an excess of fluid albumen and in solutions of alkaline chlorids. It readily combines with metallic chlorids, to form soluble double chlorids, called **chloromercurates** or **chlorhydrargyrates**. One of these, obtained in flattened, rhombic prisms, by the cooling of a boiling solution of  $\text{HgCl}_2$  and  $\text{NH}_4\text{Cl}$ , has the composition  $\text{HgCl}_2 \cdot 2(\text{NH}_4\text{Cl}) + \text{Aq}$ , and was formerly known as *sal alembroth* or *sal sapientie*.

**Mercurammonium Chlorid**—*Mercury chloramidid*—*Infusible white precipitate*—*Ammoniated mercury*—**Hydrargyrum ammoniatum (U. S.; Br.)**— $\text{NH}_2\text{HgCl}$ —251.1—is prepared by adding a slight excess of  $\text{NH}_4\text{HO}$  to a solution of  $\text{HgCl}_2$ . It is a white powder, insoluble in alcohol, ether, and cold  $\text{H}_2\text{O}$ ; decomposed by hot  $\text{H}_2\text{O}$ , with separation of a heavy, yellow powder. It is entirely volatile, without fusion. The *fusible white precipitate* is formed in small crystals when a solution containing equal parts of  $\text{HgCl}_2$  and  $\text{NH}_4\text{Cl}$  is decomposed by  $\text{Na}_2\text{CO}_3$ . It is **mercurdiammonium chlorid**,  $\text{NH}_2\text{HgCl} \cdot \text{NH}_4\text{Cl}$ .

**Iodids.**—**Mercurous Iodid**—*Protoiodid* or *yellow iodid*—**Hydrargyri iodidum viride (U. S.; Br.)**— $\text{Hg}_2\text{I}_2$ —653.4—is prepared by grinding together 200 pts.  $\text{Hg}$  and 127 pts.  $\text{I}$  with a little alcohol,

until a green paste is formed. It is a greenish-yellow, amorphous powder, insoluble in  $H_2O$  and in alcohol. When heated, it turns brown, and volatilizes completely. When exposed to light, or even after a time in the dark, it is decomposed into  $HgI_2$  and  $Hg$ . The same decomposition is brought about instantly by  $KI$ ; more slowly by solutions of alkaline chlorids, and by  $HCl$  when heated.  $NH_4HO$  dissolves it with separation of a gray precipitate.

**Mercuric Iodid**—*Biniodid* or *red iodid*—**Hydrargyri iodidum rubrum** (U. S. ; Br.)— $HgI_2$ —453.7—is obtained by double decomposition between  $HgCl_2$  and  $KI$ , care being had to avoid too great an excess of the alkaline iodid, that the soluble potassium iodhydrargyrate may not be formed.

It is sparingly soluble in  $H_2O$ ; but forms colorless solutions with alcohol. It dissolves readily in many dilute acids, and in solutions of ammoniacal salts, alkaline chlorids, and mercuric salts; and in solutions of alkaline iodids. Iron and copper convert it into  $(Hg_2)I_2$ , then into  $Hg$ . The hydrates of  $K$  and  $Na$  decompose it into oxid or oxyiodid, and combine with another portion to form iodhydrargyrates, which dissolve.  $NH_4HO$  separates from its solution a brown powder, and forms a yellow solution, which deposits white flocks.

**Cyanids.**—**Mercuric Cyanid**—**Hydrargyri cyanidum** (U. S.)— $Hg(CN)_2$ —251.7—is best prepared by heating together, for a quarter of an hour, potassium ferrocyanid, 1 pt.;  $HgSO_4$ , 2 pts.; and  $H_2O$ , 8 pts. It crystallizes in quadrangular prisms; soluble in 8 pts. of cold  $H_2O$ , much less soluble in alcohol; highly poisonous. When heated dry it blackens, and is decomposed into  $(CN)_2$  and  $Hg$ ; if heated in presence of  $H_2O$  it yields  $HCN$ ,  $Hg$ ,  $CO_2$ , and  $NH_3$ . Hot concentrated  $H_2SO_4$ , and  $HCl$ ,  $HBr$ ,  $HI$ , and  $H_2S$  in the cold decompose it, with liberation of  $HCN$ . It is not decomposed by alkalies.

**Nitrates.**—There exist, besides the normal nitrates:  $(Hg_2)(NO_3)_2$ , and  $Hg(NO_3)_2$ , three basic mercurous nitrates, three basic mercuric nitrates, and a mercurioso-mercuric nitrate.

**Mercurous Nitrate**— $(Hg_2)(NO_3)_2 + 2 Aq$ —523.4+36—is formed when excess of  $Hg$  is digested with  $HNO_3$ , diluted with  $\frac{1}{2}$  vol.  $H_2O$ ; until short, prismatic crystals separate.

It effloresces in air; fuses at  $70^\circ$  ( $158^\circ F.$ ); dissolves in a small quantity of hot  $H_2O$ , but with a larger quantity is decomposed with separation of the yellow, basic trimercuric nitrate  $Hg(NO_3)_2$ ,  $2HgO + Aq$ .

**Dimercurous Nitrate**— $(Hg_2)(NO_3)_2$ ,  $Hg_2O + Aq$ —938.8+18—is formed by acting upon the preceding salt with cold  $H_2O$  until it turns lemon-yellow; or by extracting with cold  $H_2O$  the residue of evaporation of the product obtained by acting upon excess of  $Hg$  with concentrated  $HNO_3$ .

**Trimercurous Nitrate**— $(\text{Hg}_2)_2(\text{NO}_3)_4$ ,  $\text{Hg}_2\text{O} + 3 \text{ Aq}$ —1462.2+54—is obtained in large, rhombic prisms, when excess of Hg is boiled with  $\text{HNO}_3$ , diluted with 5 pts.  $\text{H}_2\text{O}$ , for 5-6 hours, the loss by evaporation being made up from time to time.

**Mercuric Nitrate**— $\text{Hg}(\text{NO}_3)_2$ —323.7—is formed when Hg or  $\text{HgO}$  is dissolved in excess of  $\text{HNO}_3$ , and the solution evaporated at a gentle heat. A syrupy liquid is obtained, which, over quick-lime, deposits large, deliquescent crystals, having the composition  $2[\text{Hg}(\text{NO}_3)_2] + \text{Aq}$ , while there remains an uncrystallizable liquid,  $\text{Hg}(\text{NO}_3)_2 + 2 \text{ Aq}$ .

This salt is soluble in  $\text{H}_2\text{O}$ , and exists in the **Liq. hydrargyri nitratis** (**U. S.**), **Liq. hydrargyri nitratis acidus** (**Br.**); in the volumetric standard solution used in *Liebig's process* for urea; and probably in *citrine ointment*=**Ung. hydrar. nitratis** (**U. S.**; **Br.**).

**Dimercuric Nitrate**— $\text{Hg}(\text{NO}_3)_2$ ,  $\text{HgO} + \text{Aq}$ —539.4—is formed when  $\text{HgO}$  is dissolved to saturation in hot  $\text{HNO}_3$ , diluted with 1 vol.  $\text{H}_2\text{O}$ ; and crystallizes on cooling. It is decomposed by  $\text{H}_2\text{O}$  into trimercuric nitrate,  $\text{Hg}(\text{NO}_3)_2$ ,  $2\text{HgO}$ , and  $\text{Hg}(\text{NO}_3)_2$ .

**Hexamercuric Nitrate**— $\text{Hg}(\text{NO}_3)_2$ ,  $5 \text{ HgO}$ —1402.2—is formed as a red powder, by the action of  $\text{H}_2\text{O}$  on trimercuric nitrate.

**Sulphates.**—**Mercurous Sulphate**— $(\text{Hg}_2)\text{SO}_4$ —495.4—is a white, crystalline powder, formed by gently heating together 2 pts. Hg and 3 pts.  $\text{H}_2\text{SO}_4$ , and causing the product to combine with 2 pts. Hg. Heated with  $\text{NaCl}$  it forms  $(\text{Hg}_2)\text{Cl}_2$ .

**Mercuric Sulphate**—**Hydrargyri sulphas** (**Br.**)— $\text{HgSO}_4$ —295.7—is obtained by heating together Hg and  $\text{H}_2\text{SO}_4$ , or Hg,  $\text{H}_2\text{SO}_4$ , and  $\text{HNO}_3$ . It is a white, crystalline, anhydrous powder, which, on contact with  $\text{H}_2\text{O}$ , is decomposed with formation of trimercuric sulphate,  $\text{HgSO}_4, 2\text{HgO}$ ; a yellow, insoluble powder, known as **turpeth mineral**=**Hydrargyri subsulphas flavus** (**U. S.**).

**Analytical Characters.**—**MERCUROUS.**—(1.) Hydrochloric acid: white ppt.; insoluble in  $\text{H}_2\text{O}$  and in acids; turns black with  $\text{NH}_4 \text{HO}$ ; when boiled with  $\text{HCl}$ , deposits Hg, while  $\text{HgCl}_2$  dissolves. (2.) Hydrogen sulphid: black ppt.; insoluble in alkaline sulphhydrates, in dilute acids, and in  $\text{KCN}$ ; partly soluble in boiling  $\text{HNO}_3$ . (3.) Potash: black ppt.; insoluble in excess. (4.) Potassium iodid: greenish ppt.; converted by excess into Hg, which is deposited, and  $\text{HgI}_2$ , which dissolves.

**MERCURIC.**—(1.) Hydrogen sulphid: black ppt. If the reagent be slowly added, the ppt. is first white, then orange, finally black. (2.) Ammonium sulphhydrate: black ppt.; insoluble in excess, except in the presence of organic matter. (3.) Potash or soda: yellow ppt.; insoluble in excess. (4.) Ammonium hydrate: white ppt.; soluble in great excess and in solutions of  $\text{NH}_4$  salts. (5.) Potassium carbonate: red ppt. (6.) Potassium iodid: yellow ppt.,

rapidly turning to salmon color, then to red; easily soluble in excess of KI, or in great excess of mercuric salt. (7.) Stannous chlorid: in small quantity white ppt.; in larger quantity gray ppt.; and when boiled, deposit of globules of Hg.

**Action on the Economy.**—Mercury, in the metallic form, is without action upon the animal economy so long as it remains such. On contact, however, with alkaline chlorids it is converted into a soluble double chlorid, and this the more readily the greater the degree of subdivision of the metal. The mercurials insoluble in dilute HCl are also inert until they are converted into soluble compounds.

Mercuric chlorid, a substance into which many other compounds of Hg are converted when taken into the stomach or applied to the skin, not only has a distinctly corrosive action, by virtue of its tendency to unite with albuminoids, but, when absorbed, it produces well-marked poisonous effects, somewhat similar to those of arsenical poisoning. Indeed, owing to its corrosive action, and to its greater solubility, and more rapid absorption, it is a more dangerous poison than  $\text{As}_2\text{O}_3$ . In poisoning by  $\text{HgCl}_2$ , the symptoms begin sooner after the ingestion of the poison than in arsenical poisoning, and those phenomena referable to the local action of the toxic are more intense.

The treatment should consist in the administration of white of egg, not in too great quantity, and the removal of the compound formed, by emesis, before it has had time to redissolve in the alkaline chlorids contained in the stomach.

Absorbed Hg tends to remain in the system in combination with albuminoids, from which it may be set free, or, more properly, brought into soluble combination, at a period quite removed from the date of last administration, by the exhibition of alkaline iodids.

Mercury is eliminated principally by the saliva and urine, in which it may be readily detected. The fluid is faintly acidulated with HCl, and in it is immersed a short bar of Zn, around which a spiral of dentist's gold-foil is wound in such a way as to expose alternate surfaces of Zn and Au. After 24 hours, if the saliva or urine contain Hg, the Au will be whitened by amalgamation; and, if dried and heated in the closed end of a small glass tube, will give off Hg, which condenses in globules, visible with the aid of a magnifier, in the cold part of the tube.

## COMPOUNDS OF CARBON.

## Organic Substances.

In the seventeenth and eighteenth centuries, chemists had observed that there might be extracted from animal and vegetable bodies substances which differed much in their properties from those which could be obtained from the mineral world; substances which burned without leaving a residue, and many of which were subject to the peculiar changes wrought by the processes of fermentation and putrefaction. It was not until the beginning of the present century, however, that chemistry was divided into the two sections of *inorganic* and *organic*.

In the latter class were included all such substances as existed only in the organized bodies of animals and vegetables, and which seemed to be of a different essence from that of mineral bodies, as chemists had been unable to produce any of these organic substances by artificial means. Later in the history of the science it was found that these bodies were all made up of a very few elements, and that they all contained carbon.

Gmelin at this time proposed to consider as organic substances all such as contained more than one atom of C, his object in thus limiting the minimum number of atoms of C being that substances containing one atom of C, such as carbon dioxid and marsh-gas, were formed in the mineral kingdom, and consequently, according to then existing views, could not be considered as *organic*. Such a distinction, still adhered to in text-books of very recent date, of necessity leads to most incongruous results. Under it the first terms of the homologous series (see p. 224) of saturated hydrocarbons,  $\text{CH}_4$ , alcohols,  $\text{CH}_3\text{O}$ , acids,  $\text{CH}_2\text{O}_2$ , and all of their derivatives are classed among mineral substances, while all the higher terms of the same series are organic. Under it urea,  $\text{COH}_4\text{N}_2$ , the chief product of excretion of the animal body, is a mineral substance, but ethene,  $\text{C}_2\text{H}_4$ , obtained from the distillation of coal, is organic.

The idea of organic chemistry conveyed by the definition: "that branch of the science of chemistry which treats of the carbon compounds containing hydrogen," adopted in a text-book of medical chemistry printed during the present year (1890), is still more fantastic. Under it hydrocyanic acid,  $\text{CNH}$ , is "organic," but the cyanids,  $\text{CNK}$ , are "mineral." Oxalic acid,  $\text{C}_2\text{O}_4\text{H}_2$ , is "organic," and potassium hydrate,  $\text{KHO}$ , unquestionably "mineral." If these two act upon each other in the proportion of 90 parts of the former to 56 of the latter, the "organic" monopo-

tassic oxalate,  $C_2O_4HK$ , is formed, but if the proportion of  $KHO$  be doubled, other conditions remaining the same, the "mineral" dipotassic oxalate,  $C_2O_4K_2$ , is produced. Similarly one of the sodium carbonates,  $Na_2CO_3$ , is "mineral;" the other,  $NaHCO_3$ , is "organic."

The notion that organic substances could only be formed by some mysterious agency, manifested only in organized beings, was finally exploded by the labors of Wöhler and Kolbe. The former obtained urea from ammonium cyanate: while the latter, at a subsequent period, formed acetic acid, using in its preparation only such unmistakably mineral substances as coal, sulphur, aqua regia, and water.

During the half-century following Wöhler's first synthesis, chemists have succeeded not only in making from mineral materials many of the substances previously only formed in the laboratory of nature, but have also produced a vast number of carbon compounds which were previously unknown, and which, so far as we know, have no existence in nature.

At the present time, therefore, we must consider as an organic substance any compound containing carbon, whatever may be its origin and whatever its properties. Indeed, the name *organic* is retained merely as a matter of convenience, and not in any way as indicating the origin of these compounds. Although, owing to the great number of the carbon compounds, it is still convenient to treat of them as forming a section by themselves, their relations with the compounds of other elements are frequently very close. Indeed, within the past few years, compounds of silicon have been obtained, which indicate the possibility that that element is capable of forming series of compounds as interesting in numbers and variety as those of carbon.

Nevertheless, there are certain peculiarities exhibited by C in its compounds, which are not possessed to a like extent by any other element, and which render the study of organic substances peculiarly interesting and profitable.

In the study of the compounds of the other elements, we have to deal with a small number of substances, relatively speaking, formed by the union with each other of a large number of elements. With the organic substances the reverse is the case. Although compounds have been formed which contain C along with each of the other elements, the great majority of the organic substances are made up of C, combined with a very few other elements; H, O and N occurring in them most frequently.

It is chiefly in the study of the carbon compounds that we have to deal with **radicals** (see p. 49). Among mineral substances there are many whose molecules consist simply of a combination of two atoms. Among organic substances there is none which does not

contain a radical : indeed, organic chemistry has been defined as "the chemistry of compound radicals."

The atoms of carbon possess in a higher degree than those of any other element the power of uniting with each other, and in so doing of interchanging valences. Were it not for this property of the C atoms, we could have but one saturated compound of carbon and hydrogen,  $\text{CH}_4$ , or, expressed graphically :

There exist, however, a great number of such compounds, which differ from each other by one atom of C and two atoms of H. In these substances the atoms of C may be considered as linked together in a continuous chain, their free valences being satisfied by H atoms ; thus :

If now one H atom be removed from either of these combinations, we have a group possessing one free valence, and consequently univalent. The decompositions of these substances show that they contain such radicals, and that their typical formulæ are :

**Homologous Series.**—It will be observed that these formulæ differ from each other by  $\text{CH}_2$ , or some multiple of  $\text{CH}_2$ , more or less. In examining numbers of organic substances, which are closely related to each other in their properties, we find that we can arrange the great majority of them in series, each term of which differs from the one below it by  $\text{CH}_2$ ; such a series is called an **homologous series**. It will be readily understood that such an arrangement in series vastly facilitates the remembering of the composition of organic bodies. In the following table, for example, are given the saturated hydrocarbons, and their more immediate derivatives. At the head of each vertical column is an algebraic formula, which is the **general formula** of the entire series below it;  $n$  being equal to the numerical position in the series.

## HOMOLOGOUS SERIES.

Saturated hydrocarbons, $C_nH_{2n+2}$ .	Alcohols, $C_nH_{2n+2}O$ .	Aldehydes, $C_nH_{2n}O$ .	Acids, $C_nH_{2n}O_2$ .	Ketones, $C_nH_{2n}O$ .
$CH_4$	$CH_4O$	.....	$CO_2H_2$	.....
$C_2H_6$	$C_2H_6O$	$C_2H_4O$	$C_2O_2H_4$	.....
$C_3H_8$	$C_3H_8O$	$C_3H_6O$	$C_3O_2H_6$	$C_3H_6O$
$C_4H_{10}$	$C_4H_{10}O$	$C_4H_8O$	$C_4O_2H_8$	$C_4H_8O$
$C_5H_{12}$	$C_5H_{12}O$	$C_5H_{10}O$	$C_5O_2H_{10}$	$C_5H_{10}O$
$C_6H_{14}$	$C_6H_{14}O$	$C_6H_{12}O$	$C_6O_2H_{12}$	.....
$C_7H_{16}$	$C_7H_{16}O$	$C_7H_{14}O$	$C_7O_2H_{14}$	.....
$C_8H_{18}$	$C_8H_{18}O$	$C_8H_{16}O$	$C_8O_2H_{16}$	.....
$C_9H_{20}$	$C_9H_{20}O$	.....	$C_9O_2H_{18}$	.....
$C_{10}H_{22}$	$C_{10}H_{22}O$	.....	$C_{10}O_2H_{20}$	.....
$C_{11}H_{24}$	.....	.....	.....	.....
$C_{12}H_{26}$	.....	.....	$C_{12}O_2H_{24}$	.....
$C_{13}H_{28}$	.....	.....	.....	.....
$C_{14}H_{30}$	.....	.....	$C_{14}O_2H_{28}$	.....

But the arrangement in homologous series does more for us than this. The properties of substances in the same series are similar, or vary in regular gradation according to their position in the series. Thus, in the series of monoatomic alcohols (see above) each member yields on oxidation, first an aldehyde, then an acid. Each yields a series of compound ethers by the action of acids upon it. The boiling-points of the first six are, 66°.5, 78°.4, 96°.7, 111°.7, 132°.2, 153°.9; from which it will be seen that the boiling-point of any one of them can be determined, with a maximum error of 3°, by taking the mean of those of its neighbors above and below. In this way we may prophesy, to some extent, the properties of a wanting member in a series before its discovery.

The terms of any homologous series must all have the same constitution, *i.e.*, their constituent atoms must be similarly arranged within the molecule.

**Isomerism—Metamerism—Polymerism.**—Two substances are said to be isomeric, or to be isomeres of each other, when they have the same centesimal composition. If, for instance, we analyze acetic acid and methyl formiate, we find that each body consists of C, O and H, in the following proportions:

Carbon .....	40	$24 = 12 \times 2$
Oxygen .....	53.33	$32 = 16 \times 2$
Hydrogen.....	6.67	$4 = 1 \times 4$
	<hr/>	<hr/>
	100.00	60

This similarity of centesimal composition may occur in two ways. The two substances may each contain in a molecule the same numbers of each kind of atom ; or one may contain in each molecule the same kind of atoms as the other, but in a higher multiple. In the above instance, for example, each substance may have the composition  $C_2H_4O_2$ ; or one may have that formula and the other,  $C_6H_{12}O_6$ , or  $C_2H_4O_2 \times 3$ . In the former case the substances are said to be **metameric**, in the latter **polymeric**. Whether two substances are metameric or polymeric can only be determined by ascertaining the weights of their molecules, which is usually accomplished by determining the sp. gr. of their vapors (see p. 37).

The sp. gr. of the vapor of acetic acid is the same as that of methyl formiate, and, consequently, each substance is made up of molecules, each containing  $C_2H_4O_2$ . But the two substances differ from each other greatly in their properties, and their differences are at once indicated by their typical or graphic formulæ :

or graphically :

**Classification of Organic Substances.**—The practically unlimited number of carbon compounds which are known to exist, or whose existence is possible according to accepted theories, imposes the necessity of a rational classification, that they may be satisfactorily studied and that their reactions and decompositions may be understood. Such a classification has been constructed, embracing not only known compounds, but capable of extension, to include in a systematic whole, any compounds which may be discovered in the future. The rules governing the naming of organic substances constitute a part of the system ; and the names used, cumbrous and barbarous as they may seem to the uninitiated, indicate to the educated not only the constitution of the substance, but also its position in the classification, its relationship to other bodies, and the reactions and decompositions of which it is capable or incapable.

The simplest of the carbon compounds, the **hydrocarbons**, or substances consisting of carbon and hydrogen only, form the framework of the classification, and are divided into families and groups, according to the relations of the carbon and hydrogen atoms in the structure of the molecule :

**Family I.—Arborescent, acyclic, or open chain hydrocarbons.**—In the hydrocarbons of this family the number of hydrogen atoms, or this number, plus the number of univalent atoms that can be introduced into the molecule by addition (*i.e.*, by the introduction of other atoms without the removal of any already contained in the molecule) is equal to twice the number of carbon atoms plus two. Or, if  $n$  = the number of carbon atoms, and  $x$  = the number of univalent atoms which the molecule can receive by addition, these hydrocarbons will have the algebraic formula:  $C_nH_{(2n+2-x)}$ .

**Group A—Paraffin, or Methane Series.**—These are the most highly saturated hydrocarbons possible. Their algebraic formula is  $C_nH_{2n+2}$ . The graphic formulæ of the first, second and fourth are given on p. 224.

**Group B—Olefin, Ethene, or Ethylene Series**—contain two atoms of hydrogen less than the corresponding paraffins and have the algebraic formula  $C_nH_{2n}$ . No compound of this series containing a single C atom can exist. The first term is  $H_2C = CH_2$ .

**Group C—Acetylene, or Ethine Series**—contain two atoms of hydrogen less than the corresponding olefins. Their algebraic formula is  $C_nH_{2n-2}$ . The first term is  $HC \equiv CH$ .

**Family II.—Cyclic or Closed Chain Hydrocarbons.**—The compounds of this family all contain a "nucleus" or "ring," in which every carbon atom is linked to at least two other carbon atoms, thus forming a "cycle," or closed chain. The number of possible groups in this series is very large. Representatives of the following are known:

**Group A — Paraffene Series** — have the algebraic formula  $C_nH_{2n}$ . This is the simplest form of cyclic hydrocarbon, each carbon atom exchanging a valence with its neighbor on each side. Some representatives of the group exist in petroleum and have been formed synthetically. They are isomeric with the terms of Group B, Family I.

**Group B—Terebenthic Series**—have the algebraic formula  $C_nH_{2n-4}$ . The lower terms of the series are not well known. Among the higher terms are a great number of isomeres existing in nature among the essential oils.

**Group C—Benzenic Series.**—This series includes the most important of the closed chain hydrocarbons, and their derivatives. They have the algebraic formula  $C_nH_{2n-6}$ , and all contain the benzene nucleus  $C_6H_6$ , or some product of substitution thereof. The number of derivatives obtainable by substitution, by grafting together of two or more benzene nuclei, or by grafting of open-chain hydrocarbons, or of their derivatives, upon a benzol

nucleus is apparently unlimited. They are all very stable substances.

The other carbon compounds may be regarded as derived from the hydrocarbons by the substitution or addition of an atom or group of atoms in or upon the hydrocarbon, the character, or **function** of the substance so produced depending upon the character and position of the substituted or added atom or group. This will be developed as we proceed.

## ACYCLIC HYDROCARBONS AND THEIR DERIVATIVES.

## FIRST SERIES OF HYDROCARBONS.

SERIES  $C_nH_{2n+2}$ .

The hydrocarbons of this series at present known are the following :

Name.	Formula.	Specific Gravity of Liquid.	Boiling-point, Centigrade.
Methyl hydrid.....	$CH_3H$	.....	.....
Ethyl hydrid.....	$C_2H_5H$	.....	.....
Propyl hydrid.....	$C_3H_7H$	.....	.....
Butyl hydrid.....	$C_4H_9H$	0.600 at 0°	0°
Amyl hydrid.....	$C_5H_{11}H$	0.628 at 18°	30°
Hexyl hydrid.....	$C_6H_{13}H$	0.669 at 18°	68°
Heptyl hydrid.....	$C_7H_{15}H$	0.690 at 18°	92°-94°
Octyl hydrid.....	$C_8H_{17}H$	0.726 at 18°	116°-118°
Nonyl hydrid.....	$C_9H_{19}H$	0.741 at 18°	136°-138°
Decyl hydrid.....	$C_{10}H_{21}H$	0.757 at 18°	158°-162°
Undecyl hydrid.....	$C_{11}H_{23}H$	0.766 at 18°	180°-182°
Dodecyl hydrid.....	$C_{12}H_{25}H$	0.778 at 18°	198°-200°
Tridecyl hydrid.....	$C_{13}H_{27}H$	0.796 at 18°	218°-220°
Tetradecyl hydrid....	$C_{14}H_{29}H$	0.809 at 18°	236°-240°
Pentadecyl hydrid....	$C_{15}H_{31}H$	0.825 at 18°	258°-262°
Hexadecyl hydrid.....	$C_{16}H_{33}H$	.....	about 280°

They form an homologous series whose general formula is  $C_nH_{2n+2}$ , and are known as **paraffins** from their stability (*parum* = little, *affinis* = affinity). The *radicals*  $C_nH_{2n+1}$ , of which they are the **hydrids**, are sometimes designated as the radicals of the monoatomic alcohols, or monoatomic alcoholic radicals.

Corresponding to the higher terms of the series (those above the third) there are one or more isomeres, which may be arranged in four classes. (1.) The **normal paraffins**, or regularly formed series, in which each C atom is linked to two other C atoms. (2.) The **isoparaffins**, those in which one C atom is linked to three others. (3.) The **neoparaffins**, those in which two C atoms are each linked to three others. (4.) The **mesoparaffins**, those in which one C atom is linked to four others. The constitution of these series is explained by the graphic formulæ :

The number of possible isomeres increases rapidly with an increasing number of carbon atoms. It has been calculated that the number of possible isomeres with increasing values of  $n$  are as follows :

$n = 1$	$n = 2$	$n = 3$	$n = 4$	$n = 5$	$n = 6$
1	1	1	2	3	5
$n = 7$	$n = 8$	$n = 9$	$n = 10$	$n = 11$	$n = 12$
9	18	35	75	159	357

Many of these hydrocarbons exist in nature, in petroleum, and in the gases accompanying it. They may be produced by the following **general reactions** :

1.) By the action of zinc, either alone, at elevated temperatures, or in the presence of  $\text{H}_2\text{O}$ , upon the corresponding iodids :

or

2.) By electrolysis of the corresponding fatty acid :

3.) By the action of the organo-zincic derivative upon the iodid of the alcoholic radical, upon the corresponding olefin iodid, or upon the allylic iodid.

4.) By the action of highly concentrated hydriodic acid at  $275^\circ$ – $300^\circ$  ( $527^\circ$ – $572^\circ$  F.) upon hydrocarbons of the ethene and ethine series, upon alcohols, amins, etc. This is a method of hydrogenation applicable in many other cases.

5.) By the destructive distillation of many organic substances.

**General properties.**—They are gaseous, liquid, or solid, and have sp. gr. and boiling points increasing with the number of C atoms (see table, p. 229). They are lighter than  $\text{H}_2\text{O}$ , neutral, insoluble in  $\text{H}_2\text{O}$ , soluble in alcohol, ether, and in liquid hydrocarbons. Their odor is faint and not unpleasant.

They are very stable and incapable of modification by addition. Chlorin and bromin decompose them, with formation of products of substitution. They are inflammable and burn with a luminous flame. Nitric acid forms nitro-derivatives with the higher terms.

**Methyl hydrid—Methane—Marsh-gas—Light carburetted hydrogen—Fire-damp— $\text{CH}_4$ —16**—is given off in swamps as a product of decomposition of vegetable matter, in coal mines, and in the gases issuing from the earth in the vicinity of petroleum deposits. Coal-gas contains it in the proportion of 36-50 per cent. It may be prepared by strongly heating a mixture of sodium acetate with sodium hydrate and quicklime.

It is a colorless, odorless, tasteless gas; very sparingly soluble in  $\text{H}_2\text{O}$ : sp. gr. 0.559... At high temperatures it is decomposed into C and H. It burns in air with a pale yellow flame. Mixed with air or O it explodes violently on contact with flame, producing water and carbon dioxid; the latter constituting the **after-damp** of miners. It is not affected by Cl in the dark, but, under the influence of diffuse daylight, one or more of the H atoms are displaced by an equivalent quantity of Cl. In direct sunlight the substitution is accompanied by an explosion.

**Petroleum.**—Crude petroleum differs in composition and in physical properties in the products of different wells, even in the same section of country. It varies in color from a faintly yellowish tinge to a dark brown, nearly black, with greenish reflections. The lighter-colored varieties are limpid, and the more highly colored of the consistency of thin syrup. The sp. gr. varies from 0.74 to 0.92. Crude petroleum contains all the hydrocarbons mentioned in the list on p. 229 (the lowest terms of the series being found in the gases accompanying petroleum and held in solution by the oil under the pressure it supports in natural pockets), besides hydrocarbons of the olefin, paraffene, and benzene series. They also contain varying quantities of sulphur compounds, which communicate a disgusting odor to some oils.

The crude oil is highly inflammable, usually highly colored, and is prepared for its multitudinous uses in the arts by the processes of distillation and refining. The products of lowest boiling point are usually consumed, but are sometimes condensed.

The principal products of petroleum are: **Petroleum ether I.**, or **Cymogene**, boils at  $0^\circ$  ( $32^\circ \text{F.}$ ), used in ice machines; **Petroleum ether II.**, or **Rhigolene**, a highly inflammable liquid, sp. gr. about 0.60, boils at about  $20^\circ$  ( $68^\circ \text{F.}$ ), used to produce cold by its rapid evaporation, and as a solvent. Its use in the vicinity of flame is attended with danger. **Gasolene** boils from  $45^\circ$  ( $113^\circ \text{F.}$ )

to 76° (168°.8 F.) ; used as a fuel and for the manufacture of "air gas." **Naphtha**, divided into three grades, C, B, and A, boils from 82°.2 (180 F.) to 148°.8 (300 F.) ; used as a solvent for fats, etc., and in the manufacture of "water gas." Sometimes called "safety oil." **Benzine**, or **benzolene**, boils from 148° (298 F.) to 160° (320 F.) ; used as a solvent in making paints and varnishes. The most important product of petroleum is that portion which distills between 176° (349 F.) and 218° (424 F.) and which constitutes **kerosene** and other oils used for burning in lamps. An oil to be safely used for burning in lamps should not "flash," or give off inflammable vapor, below 37°.4 (100 F.), and should not burn at temperatures below 149° (300° F.).

From the residue remaining after the separation of the kerosene, many other products are obtained. **Lubricating oils**, of too high boiling-point for use in lamps. **Paraffin**, a white, crystalline solid, fusible at 45–65° (113–149° F.), which is used in the arts for a variety of purposes formerly served by wax, such as the manufacture of candles. In the laboratory it is very useful for coating the glass stoppers of bottles, and for other purposes, as it is not affected by acids or by alkalies. It is odorless, tasteless, insoluble in  $H_2O$  and in cold alcohol ; soluble in boiling alcohol and in ether, fatty and volatile oils, and mineral oils. It is also obtained by the distillation of certain varieties of coal, and is found in nature in **fossil wax** or **ozocerite**.

The products known as **vaseline**, **petrolatum** (U. S.), **cosmoline**, etc., which are now so largely used in pharmacy and perfumery, are mixtures of paraffin and the heavier petroleum oils. Like petroleum itself, its various commercial derivatives are not definite compounds, but mixtures of the hydrocarbons of this series.

### HALOID DERIVATIVES OF THE PARAFFINS.

By the action of Cl or Br upon the paraffins, or by the action of HCl, HBr or HI upon the corresponding hydrates, compounds are obtained in which one of the H atoms of the hydrocarbon has been replaced by an atom of Cl, Br or I :  $C_2H_6 + Br_2 = C_2H_5Br + HBr$ , or  $C_2H_5OH + HCl = C_2H_5Cl + H_2O$ . These compounds may be considered as the chlorids, bromids or iodids of the alcoholic radicals ; and are known as **haloid ethers**.

When Cl is allowed to act upon  $CH_4$ , it replaces a further number of H atoms until finally carbon tetrachlorid,  $CCl_4$ , is produced. Considering marsh gas as **methyl hydrid**,  $CH_3.H$ , the first product of substitution is **methyl chlorid**,  $CH_3.Cl$  ; the second **monochlormethyl chlorid**,  $CH_2Cl.Cl$  ; the third **dichlormethyl chlorid**, or **chloroform**,  $CHCl_2Cl$  ; and the fourth carbon **tetrachlorid**,  $CCl_4$ .

Similar derivatives are formed with Br and I and with the other hydrocarbons of the series.

**Methyl chlorid**— $\text{CH}_3\text{Cl}$ —50.5—is a colorless gas, slightly soluble in  $\text{H}_2\text{O}$ , and having a sweetish taste and odor. It is obtained by distilling together  $\text{H}_2\text{SO}_4$ , sodium chlorid and methyl alcohol. It may be condensed to a liquid which boils at  $-22^\circ$  ( $-7.6^\circ \text{F.}$ ). It burns with a greenish flame. Heated with potassium hydrate it is converted into methyl alcohol.

**Monochlormethyl chlorid**—*Methene chlorid*—*Dichloromethane*—*Methylene chlorid*—*Chloromethyl*— $\text{CH}_2\text{Cl}_2$ —85—is obtained by the action of Cl upon  $\text{CH}_3\text{Cl}$ ; or by shaking an alcoholic solution of chloroform with powdered zinc and a little ammonium hydrate. In either case the product must be purified.

It is a colorless, oily liquid, boils at  $40-42^\circ$  ( $104-107.6^\circ \text{F.}$ ); sp. gr. 1.36; its odor is similar to that of chloroform; it is very slightly soluble in  $\text{H}_2\text{O}$ ; and is not inflammable. Like most of the chlorinated derivatives of this series, it is possessed of anæsthetic powers. Its use as an anæsthetic is attended with the same (if not greater) danger as that of chloroform.

**Dichlormethyl chlorid**—*Methenyl chlorid*—*Formyl chlorid*—*Trichloromethane*—**Chloroform**—**Chloroformum** (U. S., Br.)— $\text{CHCl}_3$ —120.5—is obtained by heating in a capacious still, 35-40 litres (9-11 gall.) of  $\text{H}_2\text{O}$ , adding 5 kilos (11 lbs.) of recently slacked lime and 10 kilos (22 lbs.) of chlorid of lime; 2.5 kilos ( $2\frac{1}{2}$  qts.) of alcohol are then added and the temperature quickly raised until the product begins to distil, when the fire is withdrawn, heat being again applied toward the end of the reaction. The crude chloroform so obtained is purified, first by agitation with  $\text{H}_2\text{SO}_4$ , then by mixing with alcohol and recently ignited potassium carbonate, and distilling the mixture.

Chloroform is now extensively manufactured by the action of bleaching powder upon acetone, the reaction being expressed by the equation:  $2\text{CO}(\text{CH}_3)_2 + 6\text{CaCl}(\text{OCl}) = 2\text{CHCl}_3 + 2\text{Ca}(\text{HO})_2 + (\text{CH}_3\text{COO})_2\text{Ca} + 3\text{CaCl}_2$ .

It is a colorless, volatile liquid, having a strong, agreeable, ethereal odor, and a sweet taste; sp. gr. 1.497; very sparingly soluble in  $\text{H}_2\text{O}$ ; miscible with alcohol and ether in all proportions; boils at  $60.8^\circ$  ( $141.4^\circ \text{F.}$ ). It is a good solvent for many substances insoluble in  $\text{H}_2\text{O}$ , such as phosphorus, iodine, fats, resins, caoutchouc, gutta-percha and the alkaloids.

It ignites with difficulty, but burns from a wick with a smoky, red flame, bordered with green. It is not acted on by  $\text{H}_2\text{SO}_4$ , except after long contact, when  $\text{HCl}$  is given off. In direct sunlight Cl converts it into  $\text{CCl}_4$  and  $\text{HCl}$ . The alkalies in aqueous solution do not act upon it, but, when heated with them in alcoholic solution, it is decomposed with formation of chlorid and

formiate of the alkaline metal. When perfectly pure it is not altered by exposure to light; but if it contain compounds of N, even in very minute quantity, it is gradually decomposed by solar action into HCl, Cl and other substances.

**Impurities.**—*Alcohol*, if present in large amount, lowers the sp. gr. of the chloroform, and causes it to fall through  $H_2O$  in opaque, pearly drops. If present in small amount it produces a green color with ferrous dinitrosulphid (obtained by acting on ferrous chlorid with a mixture of potassium nitrate and ammonium hydrosulphid). *Aldehyde* produces a brown color when  $CHCl_3$  containing it is heated with liquor potassæ. *Hydrochloric acid* reddens blue litmus, and causes a white precipitate in an aqueous solution of silver nitrate shaken with chloroform. *Methyl and empyreumatic compounds* are the most dangerous of the impurities of chloroform. Their absence is recognized by the following characters: (1.) When the chloroform is shaken with an equal volume of colorless  $H_2SO_4$ , and allowed to stand 24 hours; the upper (chloroform) layer should be perfectly colorless, and the lower (acid) layer colorless or faintly yellow. (2.) When a small quantity is allowed to evaporate spontaneously, the last portions should have no pungent odor, and the remaining film of moisture should have no taste or odor other than those of chloroform.

**Analytical Characters.**—(1.) Add a little alcoholic solution of potash and 2-3 drops of anilin and warm; a disagreeable odor, resembling that of witch-hazel, is produced. (2.) Vapor of  $CHCl_3$ , when passed through a red-hot tube, is decomposed with formation of HCl and Cl, the former of which is recognized by the production of a white ppt., soluble in ammonium hydrate, in an acid solution of silver nitrate. This test does not afford reliable results when the substance tested contains a free acid and chlorids. (3.) Dissolve about 0.01 gm. of  $\beta$  naphthol in a small quantity of KHO solution, warm, and add the suspected liquid; a blue color is produced. (4.) Add about 0.3 gm. resorcin in solution, and 3 gts. NaHO solution and boil strongly. In the presence of  $CHCl_3$  or of chloral a yellowish-red color is produced, and the liquid exhibits a beautiful yellow-green fluorescence.

**Toxicology.**—The action of chloroform varies as it is taken by the stomach or by inhalation. In the former case, owing to its insolubility, but little is absorbed, and the principal action is the local irritation of the mucous surfaces. Recovery has followed a dose of four ounces, and death has been caused by one drachm, taken into the stomach. Chloroform vapor acts much more energetically, and seems to owe its potency for evil to its paralyzing influence upon the respiratory nerve centres, and upon the cardiac ganglia. While persons suffering from heart disease are particularly susceptible to the paralyzing effect of chloroform

vapor, there are many cases recorded of death from the inhalation of small quantities, properly diluted, in which no heart lesion was found upon a post-mortem examination. Chloroform is apparently not altered in the system, and is eliminated with the expired air.

No chemical antidote to chloroform is known. When it has been swallowed, the stomach-pump and emetics are indicated; when taken by inhalation, a free circulation of air should be established about the face; artificial respiration and the application of the induced current to the sides of the neck should be resorted to.

The nature of the poison is usually revealed at the autopsy by its peculiar odor, which is most noticeable on opening the cranial and thoracic cavities. In a toxicological analysis, chloroform is to be sought for especially in the lungs and blood. These are placed in a flask; if acid, neutralized with sodium carbonate; and subjected to distillation at the temperature of the water-bath. The vapors are passed through a tube of difficultly fusible glass; at first the tube is heated to redness for about an inch of its length, and test No. 2 applied to the issuing gas. The tube is then allowed to cool, and the distillate collected in a pointed tube, from the point of which any  $\text{CHCl}_3$  is removed by a pipette and tested according to Nos. 1, 3, and 4 above.

**Carbon tetrachlorid**—*Chlorocarbon*— $\text{CCl}_4$ —154—is formed by the prolonged action, in sunlight, of  $\text{Cl}$  upon  $\text{CH}_2\text{Cl}$  or  $\text{CHCl}_3$ ; or more rapidly, by passing  $\text{Cl}$ , charged with vapor of carbon disulphid, through a red-hot tube, and purifying the product.

It is a colorless, oily liquid, insoluble in  $\text{H}_2\text{O}$ ; soluble in alcohol and in ether; sp. gr. 1.56; boils at  $78^\circ$  ( $172.4^\circ \text{F.}$ ). Its vapor is decomposed at a red heat into a mixture of the dichlorid,  $\text{C}_2\text{Cl}_4$ , trichlorid,  $\text{C}_2\text{Cl}_5$ , and free  $\text{Cl}$ .

**Methyl bromid**— $\text{CH}_3\text{Br}$ —95.—A colorless liquid; sp. gr. 1.664; boils at  $13^\circ$  ( $55.4^\circ \text{F.}$ ); formed by the combined action of  $\text{P}$  and  $\text{Br}$  on methyl hydrate.

**Dibromomethyl bromid**—*Methenyl bromid*—*Formyl bromid*—**Bromoform**— $\text{CHBr}_2$ ,  $\text{Br}$ —253—is prepared by gradually adding  $\text{Br}$  to a cold solution of potassium hydrate in methyl alcohol until the liquid begins to be colored; and rectifying over calcium chlorid.

A colorless, aromatic, sweet liquid; sp. gr. 2.13; boils at  $150 - 152^\circ$  ( $302 - 306^\circ \text{F.}$ ); solidifies at  $-9^\circ$  ( $15.8^\circ \text{F.}$ ); sparingly soluble in  $\text{H}_2\text{O}$ ; soluble in alcohol and ether. Boiled with alcoholic potash it is decomposed in the same way as is  $\text{CHCl}_3$ .

Its physiological action is similar to that of  $\text{CHCl}_3$ . It occurs as an impurity of commercial  $\text{Br}$ , accompanied by carbon tetrabromid,  $\text{CBr}_4$ .

**Methyl iodid**— $\text{CH}_3\text{I}$ —142—a colorless liquid, sp. gr. 2.237; boils at 45 (113 F.); burns with difficulty, producing violet vapor of iodine. It is prepared by a process similar to that for obtaining the bromid; and is used in the anilin industry.

**Diiodomethyl iodid**—*Methenyl iodid*—*Formyl iodid*—**Iodoform**—**Iodoformum**, U. S.— $\text{CHI}_3$ —394.—Formed, like chloroform and bromoform, by the combined action of potash and the halogen upon alcohol; it is also produced by the action of I upon a great number of organic substances, and is usually prepared by heating a mixture of alkaline carbonate,  $\text{H}_2\text{O}$ , I and ethylic alcohol, and purifying the product by recrystallization from alcohol. It is also produced from acetone by making a solution containing 50 gm. KI, 6 gm. acetone, and 2 gm. NaHO in 2L.  $\text{H}_2\text{O}$  and gradually adding a dilute solution of  $\text{KClO}_3$ .

Iodoform is a solid, crystallizing in yellow, hexagonal plates, which melt at 115–120° (239–248° F.). It may be sublimed, a portion being decomposed. It is insoluble in water, acids, and alkaline solutions; soluble in alcohol, ether, carbon disulphid, and the fatty and essential oils; the solutions, when exposed to the light, undergo decomposition and assume a violet-red color. It has a sweet taste and a peculiar, penetrating odor, resembling, when the vapor is largely diluted with air, that of saffron. When heated with potash, a portion is decomposed into formiate and iodid, while another portion is carried off unaltered with the aqueous vapor. It contains 96.7% of its weight of iodine.

**Ethyl chlorid**—*Hydrochloric or muriatic ether*— $\text{C}_2\text{H}_5\text{Cl}$ —64.5.—A colorless, white, ethereal liquid; boils at 11 (51.8 F.); obtained by passing gaseous HCl through ethylic alcohol to saturation, and distilling over the water-bath.

By the continued action of Cl in the sunshine upon ethyl chlorid, or upon ethene chlorid,  $\text{C}_2\text{H}_4\text{Cl}_2$ , a white, crystalline solid, **Hexachlorethane** or **carbon trichlorid**,  $\text{C}_2\text{Cl}_6$ , is produced. It is insoluble in  $\text{H}_2\text{O}$ , soluble in alcohol and in ether, has an aromatic odor, fuses at 160° (320° F.), and boils at 182° (359.6 F.).

**Ethyl bromid**—*Hydrobromic ether*— $\text{C}_2\text{H}_5\text{Br}$ —109.—A colorless, ethereal liquid; boils at 40.7 (105.3 F.); obtained by the combined action of P and Br on ethylic alcohol.

**Ethyl iodid**—*Hydriodic ether*— $\text{C}_2\text{H}_5\text{I}$ —156—is prepared by placing absolute alcohol and P in a vessel surrounded by a freezing mixture and gradually adding I; when the action has ceased, the liquid is decanted, distilled over the water-bath, and the distillate washed and rectified.

It is a colorless liquid; boils at 72.2 (162° F.); has a powerful, ethereal odor; burns with difficulty. It is largely used in the anilin industry.

## MONOATOMIC ALCOHOLS.

SERIES  $C_nH_{2n+2}O$ .

The name **alcohol**, formerly applied only to the substances now popularly so called, has gradually come to be used to designate a large class of important bodies, of which vinic alcohol is the representative. These substances are mainly characterized by their power of entering into double decomposition with acids, to form neutral compounds, called **compound ethers**, water being at the same time formed, at the expense of both alcohol and acid. They are the **hydrates** of hydrocarbon radicals, and as such resemble the metallic hydrates, while the compound ethers are the counterparts of the metallic salts :

As the metallic hydrates may be considered as formed by the union of one atom of the metallic element with a number of groups OH, corresponding to its valence, so the alcohols are formed by union of an unoxidized radical with a number of groups OH, equal to or less than the number of free valences of the radical. When the alcohol contains one OH, it is designated as **monoatomic**; when two, **diatomic**; when three, **triatomic**, etc.

The simplest alcohols are those of this series derivable from the saturated hydrocarbons, and having the general formula  $C_nH_{2n+2}O$ , or  $C_nH_{2n+1}OH$ . They may be formed synthetically : (1.) By acting upon the corresponding iodid with potassium hydrate :  $C_2H_5I + KHO = KI + C_2H_5OH$ . (2.) From the alcohol next below it in the series, by direct addition of  $CH_2$ , only, however, by a succession of five reactions. (3.) By the action of  $H_2SO_4$  and  $H_2O$  upon the corresponding hydrocarbon of the series  $C_nH_{2n}$ .

The saturated monoatomic alcohols are, however, not limited to one corresponding to each alcoholic radical. There exist—corresponding to the higher alcohols—a number of substances having the same centesimal composition and the same alcoholic properties, but differing in their physical characters and in their products of decomposition and oxidation. These isomeres have been the subject of much careful study of late years. It has been found that the molecules of methyl, ethyl, and other higher alco-

hols are made up of the group  $(\text{CH}_2\text{OH})'$  united to H or to  $\text{C}_n\text{H}_{2n+1}$ , thus :

and all monoatomic alcohols containing this group,  $\text{CH}_2\text{OH}$ , have been designated as **primary alcohols**. Isomeric with these are other bodies, which, in place of the group  $(\text{CH}_2\text{OH})'$ , contain the group  $(\text{CHOH})''$ , and are distinguished as **secondary alcohols**. Thus we have :

And further, other isomeric substances are known which contain the group  $(\text{COH})'''$ , and which are called **tertiary alcohols**, thus :

The alcohols of these three classes are distinguished from each other principally by their products of oxidation. The primary alcohols yield by oxidation, first an aldehyde and then an acid, each containing the same number of C atoms as the alcohol, and formed, the aldehyde by the removal of  $\text{H}_2$  from the group  $(\text{CH}_2\text{OH})$ , and the acid by the substitution of O for  $\text{H}_2$  in the same group, thus :

In the case of the secondary alcohols, the first product of oxidation is a **ketone**, containing the same number of C atoms as the alcohol, and formed by the substitution of O for HOH in the distinguishing group :

The tertiary alcohols yield by oxidation ketones or acids, whose molecules contain a less number of C atoms than the alcohol from which they are derived.

But the complication does not end here: isomeres exist corresponding to the higher alcohols, which are themselves primary alcohols, and contain the group (C<sub>2</sub>H<sub>5</sub>OH). Thus there exist no less than six distinct substances, all having the centesimal composition of amyl alcohol, C<sub>5</sub>H<sub>12</sub>O, and the properties of alcohols; and theoretical considerations point to the probable existence of two others. Of these eight substances, four are primary, three secondary alcohols, and the remaining one a tertiary alcohol. As each of these bodies contains the group of atoms characteristic of the class of alcohol to which it belongs, it is obvious that the differences observed in their properties are due to differences in the arrangement of the other atoms of the molecule. Experimental evidence, which it would require too much space to discuss in this place, has led chemists to ascribe the following formulæ of constitution to these isomeres:

*Primary amylie alcohols:*

*Secondary amylie alcohols:*

Methyl-isopropyl carbinol.

*Tertiary amyllic alcohol:*

**Methyl hydrate—Carbinol—Pyroxylic spirit—Methylic alcohol—Wood spirit—H,CH<sub>2</sub>OH—32**—may be formed from marsh-gas, CH<sub>3</sub>H, by first converting it into the iodid, and acting upon this with potassium hydrate: CH<sub>3</sub>I + KHO = KI + CH<sub>3</sub>HO. It is usually obtained by the destructive distillation of wood. The crude wood vinegar so produced is a mixture of acetic acid and methyl alcohol with a variety of other products. The crude vinegar, separated from tarry products, is redistilled; the first tenth of the distillate is treated with quicklime and again distilled; the distillate treated with dilute H<sub>2</sub>SO<sub>4</sub>; decanted and again distilled. The product, still quite impure, is the wood alcohol, wood naphtha, or pyroxylic spirit of commerce. The pure hydrate can only be obtained by decomposing a crystalline compound, such as methyl oxalate, and rectifying the product until the boiling-point is constant at 66°.5 (151°.7 F.).

Pure methyl alcohol is a colorless liquid, having an ethereal and alcoholic odor, and a sharp, burning taste; sp. gr. 0.814 at 0°; boils at 66°.5 (151°.7 F.); burns with a pale flame, giving less heat than that of ethylic alcohol; mixes with water, alcohol, and ether in all proportions; is a good solvent of resinous substances, and also dissolves sulphur, phosphorus, potash, and soda.

Methyl hydrate is not affected by exposure to air under ordinary circumstances, but in the presence of platinum-black it is oxidized, with formation of the corresponding aldehyde and acid, formic acid. Hot HNO<sub>3</sub> decomposes it with formation of nitrous fumes, formic acid and methyl nitrate. It is acted upon by H<sub>2</sub>SO<sub>4</sub> in the same way as ethyl alcohol. The organic acids form methyl ethers with it. With HCl under the influence of a galvanic current, it forms an oily substance having the composition C<sub>2</sub>H<sub>5</sub>ClO.

**Methylated spirit** is ethyl alcohol containing sufficient wood spirit to render it unfit for the manufacture of ardent spirits, by reason of the disgusting odor and taste which crude wood alcohol owes to certain empyreumatic products which it contains. Spirits so treated are not subject to the heavy duties imposed upon ordinary alcohol, and are, therefore, largely used in the arts and for the preservation of anatomical preparations. It contains one-ninth of its bulk of wood naphtha.

**Ethyl hydrate—Ethylic alcohol—Methyl Carbinol—Vinic alcohol—Alcohol—Spirits of wine— $C_2H_5HO$ —46.**

**Preparation.**—Industrially alcohol and alcoholic liquids are obtained from substances rich in starch or glucose.

The manufacture of alcohol consists of three distinct processes: 1st, the conversion of starch into sugar; 2d, the fermentation of the saccharine liquid; 3d, the separation, by distillation, of the alcohol formed by fermentation.

The raw materials for the first process are **malt** and some substance (grain, potatoes, rice, corn, etc.) containing starch. Malt is barley which has been allowed to germinate, and, at the proper stage of germination, roasted. During this growth there is developed in the barley a peculiar nitrogenous principle called **diastase**. The starchy material is mixed with a suitable quantity of malt and water, and the mass maintained at a temperature of 65–70 (149–158° F.) for two to three hours, during which the diastase rapidly converts the starch into **dextrin**, and this in turn into **glucose**.

The saccharine fluid, or **wort**, obtained in the first process, is drawn off, cooled, and **yeast** is added. As a result of the growth of the yeast-plant, a complicated series of chemical changes take place, the principal one of which is the splitting up of the glucose into carbon dioxid and alcohol:  $C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$ . There are formed at the same time small quantities of glycerin, succinic acid, and propyl, butyl, and amyl alcohols.

An aqueous fluid is thus obtained which contains 3–15 per cent. of alcohol. This is then separated by the third process, that of distillation and rectification. The apparatus used for this purpose has been so far perfected that by a single distillation an alcohol of 90–95 per cent. can be obtained.

In some cases alcohol is prepared from fluids rich in glucose, such as grape-juice, molasses, syrup, etc. In such cases the first process becomes unnecessary.

Commercial alcohol always contains  $H_2O$ , and when pure or *absolute* alcohol is required, the commercial product must be mixed with some hygroscopic solid substance, such as quicklime, from which it is distilled after having remained in contact twenty-four hours.

**Fermentation.**—This term (derived from *fervere*=to boil) was originally applied to alcoholic fermentation, by reason of the bubbling of the saccharine liquid caused by the escape of  $CO_2$ ; subsequently it came to be applied to all decompositions similarly attended by the escape of gas.

At present it is used by many authors to apply to a number of heterogeneous processes; and some writers distinguish between "true" and "false" fermentation. It is best, we believe, to limit

the application of the term to those decompositions designated as *true fermentations*.

**Fermentation** is a decomposition of an organic substance, produced by the processes of nutrition of a low form of animal or vegetable life.

The **true ferments** are therefore all organized beings, such as *torula cerevisia*, producing alcoholic fermentation; *penicillium glaucum*, producing lactic acid fermentation; and *mycoderma aceti*, producing acetic acid fermentation.

The false fermentations are not produced by an organized body, but by a soluble, unorganized, nitrogenous substance, whose method of action is as yet imperfectly understood. They may be, therefore, designated by the term **cryptolysis**. Diastase, pepsin and trypsin are **cryptolytes**.

**Properties.**—Alcohol is a thin, colorless, transparent liquid, having a spirituous odor, and a sharp, burning taste; sp. gr. 0.8095 at 0°, 0.7939 at 15° (59° F.); it boils at 78.5° (173.3° F.), and has not been solidified. At temperatures below -90° (-130° F.) it is viscous. It mixes with water in all proportions, the union being attended by elevation in temperature and contraction in volume (after cooling to the original temperature). It also attracts moisture from the air to such a degree that absolute alcohol only remains such for a very short time after its preparation. It is to this power of attracting H<sub>2</sub>O that alcohol owes its preservative power for animal substances. It is a very useful solvent, dissolving a number of gases, most of the mineral and organic acids and alkalis, most of the chlorids and carbonates, some of the nitrates, all the sulphates, essences, and resins. Alcoholic solutions of fixed medicinal substances are called **tinctures**; those of volatile principles, **spirits**.

The action of oxygen upon alcohol varies according to the conditions. Under the influence of energetic oxidants, such as chromic acid, or, when alcohol is burned in the air, the oxidation is rapid and complete, and is attended by the extrication of much heat, and the formation of carbon dioxid and water:  $C_2H_6O + 3O_2 = 2CO_2 + 3H_2O$ . Mixtures of air and vapor of alcohol explode upon contact with flame. If a less active oxidant be used, such as platinum-black, or by the action of atmospheric oxygen at low temperatures, a simple oxidation of the alcoholic radical takes place,

with formation of *acetic acid* 
$$\begin{array}{c} C_2H_5 \\ | \\ H \end{array} \left\{ \begin{array}{l} O + O_2 = \\ H \end{array} \right. \begin{array}{c} C_2H_3O \\ | \\ H \end{array} \left\{ \begin{array}{l} O + H_2O, \end{array} \right.$$

a reaction which is utilized in the manufacture of acetic acid and vinegar. If the oxidation be still further limited, *aldehyde* is formed:  $2C_2H_6O + O_2 = 2C_2H_4O + 2H_2O$ . If vapor of alcohol be passed through a tube filled with platinum sponge and heated to redness, or if a coil of heated platinum wire be introduced into

an atmosphere of alcohol vapor, the products of oxidation are quite numerous: among them are water, ethylene, aldehyde, acetylene, carbon monoxid, and acetal. Heated platinum wire introduced into vapor of alcohol continues to glow by the heat resulting from the oxidation, a fact which has been utilized in the thermocautery.

Chlorin and bromin act energetically upon alcohol, producing a number of chlorinated and brominated derivatives, the final products being *chloral* and *bromal* (q. v.). If the action of Cl be moderated, aldehyde and HCl are first produced. Iodin acts quite slowly in the cold, but old solutions of I in alcohol (tr. iodin) are found to contain HI, ethyl iodid, and other imperfectly studied products. In the presence of an alkali, I acts upon alcohol to produce iodoform. Potassium and sodium dissolve in alcohol with evolution of H: upon cooling, a white solid crystallizes, which is the double oxid of ethyl and the alkali metal, and is known as potassium or sodium ethylate. Nitric acid, aided by a gentle heat, acts violently upon alcohol, producing nitrous ether, brown fumes, and products of oxidation. (For the action of other acids upon alcohol see the corresponding ethers.) The hydrates of the alkali metals dissolve in alcohol, but react upon it slowly: the solution turns brown and contains an acetate. If alcohol be gently heated with  $\text{HNO}_3$  and nitrate of silver or of mercury, a gray precipitate falls, which is silver or mercury fulminate.

**Varieties.**—It occurs in different degrees of concentration: **absolute alcohol** is pure alcohol,  $\text{C}_2\text{H}_5\text{O}$ . It is not purchasable, and must be made as required. The so-called absolute alcohol of the shops is rarely stronger than 98 per cent. **Alcohol (U. S.)**, sp. gr. 0.820, contains 94 per cent. by volume, and **spiritus rectificatus (Br.)**, sp. gr. 0.838, contains 84 per cent. This is the ordinary rectified spirit used in the arts. **Alcohol dilutum (U. S.)**=**Spiritus tenuior (Br.)**, sp. gr. 0.920, used in the preparation of tinctures, contains 53 per cent. It is of about the same strength as the **proof spirit of commerce**.

**Analytical Characters.**—(1.) Heated with a small quantity of solution of potassium dichromate and  $\text{H}_2\text{SO}_4$ , the liquid assumes an emerald-green color, and, if the quantity of  $\text{C}_2\text{H}_5\text{O}$  be not very small, the peculiar fruity odor of aldehyde is developed. (2.) Warmed and treated with a few drops of potash solution and a small quantity of iodine, an alcoholic liquid deposits a yellow, crystalline ppt. of iodoform, either immediately or after a time. (3.) If  $\text{HNO}_3$  be added to a liquid containing  $\text{C}_2\text{H}_5\text{O}$ , nitrous ether, recognizable by its odor, is given off. If a solution of mercurous nitrate with excess of  $\text{HNO}_3$  be then added, and the mixture heated, a further evolution of nitrous ether occurs, and a yellow-

gray deposit of fulminating mercury is formed, which may be collected, washed, dried and exploded. (4.) If an alcoholic liquid be heated for a few moments with  $\text{H}_2\text{SO}_4$  diluted with  $\text{H}_2\text{O}$  and distilled, the distillate, on treatment with  $\text{H}_2\text{SO}_4$  and potassium permanganate, and afterward with sodium hyposulphite, yields aldehyde, which may be recognized by the production of a violet color with a dilute solution of fuchsin.

None of the above reactions, *taken singly*, is characteristic of alcohol.

**Action on the Economy.**—In a concentrated form alcohol exerts a dehydrating action upon animal tissues with which it comes in contact: causing coagulation of the albuminoid constituents. When diluted, ethylic alcohol may be a food, a medicine, or a poison, according to the dose and the condition of the person taking it. When taken in excessive doses, or in large doses for a long time, it produces symptoms and lesions characteristic of pure alcoholism, acute or chronic, modified or aggravated by those produced by other substances, such as amyl alcohol, which accompany it in the alcoholic fluids used as beverages. Taken in moderate quantities, with food, it aids digestion and produces a sense of comfort and exhilaration. As a medicine it is a valuable stimulant.

Much has been written concerning the value of alcohol as a food. If it have any value as such, it is as a producer of heat and force by its oxidation in the body. Experiments have failed to show that more than a small percentage (16 per cent. in 24 hrs.) of medium doses of alcohol ingested are eliminated by all channels; the remainder, therefore, disappears in the body, as the idea that it can there "accumulate" is entirely untenable. That some part should be eliminated unchanged is to be expected from the rapid diffusion and the high volatility of alcohol.

On the other hand, if alcohol be oxidized in the body, we should expect, in the absence of violent muscular exercise, an increase in temperature, and the appearance in the excreta of some product of oxidation of alcohol: aldehyde, acetic acid, carbon dioxide, or water, while the elimination of nitrogenous excreta, urea, etc., would remain unaltered or be diminished. While there is no doubt that excessive doses of alcohol produce a diminution of body temperature, the experimental evidence concerning the action in this direction of moderate doses is conflicting and incomplete. Of the products of oxidation, aldehyde has not been detected in the excreta, and acetic acid only in the intestinal canal. The elimination of carbonic acid, as such, does not seem to be increased, although positive information upon this point is wanting. If acetic acid be produced, this would form an acetate, which in turn would be oxidized to a carbonate, and eliminated

as such by the urine. The elimination of water under the influence of large doses of alcohol is greater than at other times: but whether this water is produced by the oxidation of the hydrogen of the alcohol, or is removed from the tissues by its dehydrating action, is an open question.

While physiological experiment yields only uncertain evidence, the experience of arctic travellers and others shows that the use of alcohol tends to diminish rather than increase the capacity to withstand cold. The experience of athletes and of military commanders is that intense and prolonged muscular exertion can be best performed without the use of alcohol. The experience of most literary men is that long-continued mental activity is more difficult with than without alcohol.

In cases of acute poisoning by alcohol, the stomach-pump and catheter should be used as early as possible. A plentiful supply of air, the cold douche, and strong coffee are indicated.

**Alcoholic Beverages.**—The variety of beverages in whose preparation alcoholic fermentation plays an important part is very great, and the products differ from each other materially in their composition and in their physiological action. They may be divided into four classes, the classification being based upon the sources from which they are obtained and upon the method of their preparation.

I.—Those prepared by the fermentation of malted grain—**beers, ales, and porters.**

II.—Those prepared by the fermentation of grape juice—**wines.**

III.—Those prepared by the fermentation of the juices of fruits other than the grape—**cider, fruit-wines.**

IV.—Those prepared by the distillation of some fermented saccharine liquid—**ardent spirits.**

Beer, ale, and porter are aqueous infusions or decoctions of malted grain, fermented and flavored with hops. They contain, therefore, the soluble constituents of the grain employed; dextrin and glucose, produced during the malting; alcohol and carbon dioxid, produced during the fermentation; and the soluble constituents of the flavoring material. The alcoholic strength of malt liquors varies from 1.5 to 9 per cent. Weiss beer contains 1.5–1.9 per cent.; lager, 4.1–4.5 per cent.; bock beer, 3.88–5.23 per cent.; London porter, 5.4–6.9 per cent.; Burton ale, 5.9 per cent.; Scotch ale, 8.5–9 per cent. Malt liquors all contain a considerable quantity of nitrogenous material (0.4–1 per cent. N), and succinic, lactic, and acetic acids. The amount of inorganic material, in which the phosphates of potassium, sodium, and magnesium predominate largely, varies from 0.2 to 0.3 per cent. The sp. gr. is from 1.014 to 1.033.

The adulterations of malt liquors are numerous and varied.

Sodium carbonate is added with the double purpose of neutralizing an excess of acetic acid and increasing the foam. The most serious adulteration consists in the introduction of bitter principles other than hops, and notably of strychnin, *cocculus indicus* (picrotoxin), and picric acid.

Wines are produced by the fermentation of grape-juice. In the case of red wines the *marc*, or mass of skins, seed and stems, is allowed to remain in contact with the *must*, or fermenting juice, until, by production of alcohol, the liquid dissolves a portion of the coloring matter of the skins. A certain proportion of tannin is also dissolved, whose presence is necessary to prevent *stringiness*. Sweet wines are produced from must rich in glucose, and by arresting the fermentation before that sugar has been completely decomposed. Dry wines are obtained by more complete fermentation of must less rich in glucose. Tartaric acid is the predominating acid in grape-juice, and as the proportion of alcohol increases during fermentation the acid potassium tartrate is deposited.

Most wines of good quality improve in flavor with age, and this improvement is greatly hastened by the process of *pasteuring*, which consists in warming the wine to a temperature of 60 C. (140° F.), without contact of air.

**Light wines** are those whose percentage of alcohol is less than 12 per cent. In this class are included the clarets, Sauternes, Rhine, and Moselle wines; champagnes, Burgundies, the American wines (except some varieties of California wine), Australian, Greek, Hungarian, and Italian wines.

The champagnes and some Moselle wines are sparkling, a quality which is communicated to them by bottling them before the fermentation is completed, thus retaining the carbon dioxid, which is dissolved by virtue of the pressure which it exerts. When properly prepared they are agreeable to the palate, and assist the digestion; when new, however, they are liable to communicate their fermentation to the contents of the stomach and thus seriously disturb digestion.

Of the still wines, the most widely used are the *clarets*, **Vinum rubrum** (U. S.), or red Bordeaux wines, and the *hocks*, **Vinum album** (U. S.), or white Rhine, Moselle and American wines. The former are of low alcoholic strength, mildly astringent, and contain but a small quantity of nitrogenous material, qualities which render them particularly adapted to table use and as mild stimulants. The Rhine wines are thinner and more acid, and generally of lower alcoholic strength than the clarets. The Burgundy and Rhone wines are celebrated for their high flavor and body; they are not strongly alcoholic, but contain a large quantity of nitrogenous material, to which they are indebted for their notoriety

as developers of gout. Our native American wines, particularly those of the Ohio Valley and of California, are yearly improving in flavor and quality; they more closely resemble the Rhine wines and Sauternes than other European wines.

**Heavy wines** are those whose alcoholic strength is greater than 12 per cent., usually 14 to 17 per cent.; they include the sherries, ports, Madeiras, Marsala, and some California wines, and are all the products of warm climates. Sherry is an amber-colored wine, grown in the south of Spain, *Vinum Xericum* (Br.). Marsala closely resembles sherry in appearance, and is frequently substituted for it. Port is a rich, dark red wine, grown in Portugal.

The adulteration of wine by the addition of *foreign* substances is confined almost entirely to their artificial coloration, which is produced by the most various substances, indigo, logwood, fuchsin, etc. The addition of natural constituents of wines, obtained from other sources, and the mixing of different grades of wine are, however, extensively practised. Water and alcohol are the chief substances so added; an excess of the former may be detected by the taste, and the low sp. gr. after expulsion of the alcohol. Most wines intended for export are **fortified** by the addition of alcohol. When the alcoholic spirit used is free from amyl alcohol, and is added in moderate quantities, there can be no serious objection to the practice, especially when applied to certain wines which, without such treatment, do not bear transportation. The mixing of fine grades of wine with those of a poorer quality is extensively practised, particularly with sherries, champagnes, clarets, and Burgundies, and is perfectly legitimate. The same cannot be said, however, of the manufacture of factitious wine, either entirely from materials not produced from the grape, or by converting white into red wines, or by mixing wines with coloring matters, alcohol, etc., to produce imitations of wines of a different class, an industry which flourishes extensively in Normandy, at Bingen on the Rhine, and at Hamburg. The wines so produced are usually heavy wines, port and sherry so called.

**Cider** is the fermented juice of the apple, prepared very much in the same way as wine is from grape-juice, and containing 3.5 to 7.5 per cent. of alcohol. It is very prone to acetous fermentation, which renders it sour and not only unpalatable, but liable to produce colic and diarrhoea with those not hardened to its use.

**Spirits** are alcoholic beverages, prepared by fermentation and distillation. They differ from beers and wines in containing a greater proportion of alcohol, and in not containing any of the non-volatile constituents of the grains or fruits from which they are prepared. Besides alcohol and water they contain acetic, butyric, valerianic, and cenanthic ethers, to which they owe their flavor; sometimes tannin and coloring matter derived from the

cask; amylic alcohol remaining after imperfect purification; sugar intentionally added; and caramel. It is to the last-named substance that all dark spirits owe their color: although, after long keeping in wood a naturally colorless spirit assumes a straw color.

The varieties of spirituous beverages in common use are: **Brandy, spiritus vini gallici (U. S., Br.)**, obtained by the distillation of wine, and manufactured in France and in California and Ohio. It is of sp. gr. 0.929 to 0.934, is dark or light in color, according to the quantity of burnt sugar added, and contains about 1.2 per cent. of solid matter. **American whiskey, spiritus frumenti (U. S.)**, prepared from wheat, rye, barley, or Indian corn: has a sp. gr. of 0.922 to 0.937 and contains 0.1 to 0.3 per cent. of solids. *Scotch and Irish whiskies*, colorless spirits distilled from fermented grains; sp. gr. 0.915 to 0.920, having a peculiar smoky flavor produced by drying the malted grain by a peat fire. *Gin*, also distilled from malted grain, sp. gr. 0.930 to 0.944, flavored with juniper, and sometimes fraudulently with turpentine. *Rum*, a spirit distilled from molasses, and varying in color and flavor from the dark *Jamaica rum* to the colorless *St. Croix rum*. The former is of sp. gr. 0.914 to 0.926, and contains one per cent. of solid matter.

**Liqueurs or cordials** are spirits sweetened and flavored with vegetable aromatics, and frequently colored; *anissette* is flavored with aniseed; *absinthe*, with wormwood; *curaçoa*, with orange-peel; *kirschwasser*, with cherries, the stones being cracked and the spirits distilled from the bruised fermented fruit; *kümmel*, with cummin and caraway seeds; *maraschino*, with cherries; *noyau*, with peach and apricot kernels.

**Propyl hydrate—Ethyl carbinol—Primary propyl alcohol— $\text{CH}_3$ ,  $\text{CH}_2$ ,  $\text{CH}_2\text{OH}$ —60**—is produced, along with ethylic alcohol, during fermentation, and obtained by fractional distillation of mare brandy, from *cognac oil*, *huile de marc* (not to be confounded with oil of wine), an oily matter, possessing the flavor of inferior brandy, which separates from mare brandy, distilled at high temperatures; and from the residues of manufacture of alcohol from beet-root, grain, molasses, etc. It is a colorless liquid, has a hot alcoholic taste, and a fruity odor; boils at  $96.7$  ( $206.1$  F.); and is miscible with water. It has not been put to any use in the arts. Its intoxicating and poisonous actions are greater than those of ethyl alcohol. It exists in small quantity in cider.

**Butyl alcohols— $\text{C}_4\text{H}_9\text{OH}$ —74.**—The four butyl alcohols theoretically possible are known to exist:

**Propyl carbinol—Primary normal butyl alcohol—Butyl alcohol of fermentation— $\text{CH}_3$ — $\text{CH}_2$ — $\text{CH}_2$ — $\text{CH}_2\text{OH}$** —is formed in small quantities during alcoholic fermentation, and may be obtained by repeated fractional distillation from the oily liquid left in the

rectification of vinic alcohol. It is a colorless liquid; boils at  $114.7$  ( $238.5$  F.). It is more actively poisonous than ethyl or methyl alcohol.

**Isopropyl carbinol—Isobutyl alcohol**— $\begin{array}{c} \text{CH}_3 \\ \diagup \text{CH}_2 \end{array}$ — $\text{CH—CH}_2\text{OH}$ —occurs in the fusel oil obtained in the products of fermentation and distillation of beet-root molasses. It is a colorless liquid, sp. gr.  $0.8032$ ; boils at  $110^\circ$  ( $230^\circ$  F.).

**Ethyl-methyl carbinol; secondary butyl alcohol**— $\text{CH}_3\text{—}\begin{array}{c} \text{CH}_2 \\ \diagup \text{CH} \end{array}\text{—CHOH}$ —a liquid which boils at  $99$  ( $210.2$  F.).

**Trimethyl carbinol; tertiary butyl alcohol**,  $\begin{array}{c} \text{CH}_3 \\ \diagup \text{CH}_2 \\ \diagdown \text{CH}_3 \end{array}\text{—COH}$ —a crystalline solid, which fuses at  $20-25$  ( $68-77$  F.), and boils at  $82$  ( $179.6$  F.).

**Amylic alcohols— $\text{C}_5\text{H}_{11}\text{OH}$ —88.**—Of the eight amyl alcohols theoretically possible (see p. 239) six have been obtained. The substance usually known as amylic alcohol, potato spirit, fusel oil, alcohol amylicum (Br.), is the primary alcohol  $\begin{array}{c} \text{CH}_3 \\ \diagup \text{CH}_2 \end{array}\text{—CH—CH}_2\text{—CH}_2\text{OH}$ —with lesser quantities of other alcohols, differing in nature and amount with the grain used, and the conditions of the fermentation and distillation. Each kind of "spirit" furnishing and containing a peculiar fusel.

In the process of manufacture of ardent spirits the fusel oil accumulates in great part in the still, but much of it distils over, and is more or less completely removed from the product by the process of **defuselation**.

Spirits properly freed of fusel oil give off no irritating or foul fumes, when hot. They are not colored red when mixed with three parts  $\text{C}_2\text{H}_6\text{O}$  and one part strong  $\text{H}_2\text{SO}_4$ . They are not colored red or black by ammoniacal silver nitrate solution. When 150 parts of the spirit, mixed with 1 part potash, dissolved in a little  $\text{H}_2\text{O}$ , are evaporated down to 15 parts, and mixed with an equal volume of dilute  $\text{H}_2\text{SO}_4$ , no offensive odor should be given off.

While young spirits owe their rough taste and, in great measure, their intoxicating qualities to the presence of fusel oil, it is a popular error that a spirit would be improved by complete removal of all products except ethyl alcohol. The improvement of a spirit by age is due to chemical changes in the small amount of fusel retained in a properly manufactured product, and, were this absent, the spirit would deteriorate rather than improve by age.

The individual amylic alcohols have the following characters: **Butyl carbinol; normal amylic alcohol**,  $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{OH}$ —is a colorless liquid, boils at  $135^\circ$  ( $275$  F.). Obtained

from normal butyl alcohol. It yields normal valerianic acid on oxidation.

**Isobutyl carbinol—Amyl alcohol—** $\begin{array}{c} \text{CH}_3 \\ \text{CH}_3 \end{array} \rangle \text{CH—CH}_2\text{—CH}_2\text{OH}$ —is the principal constituent of the fusel oil from grain and potatoes. It is obtained from the last milky products of rectification of alcoholic liquids. These are shaken with  $\text{H}_2\text{O}$  to remove ethyl alcohol, the supernatant oily fluid is decanted, dried by contact with fused calcium chlorid, and distilled; that portion which passes over between 128° and 132° (262°.4–269°.6 F.) being collected.

It is a colorless, oily liquid, has an acrid taste and a peculiar odor, at first not unpleasant, afterward nauseating and provocative of severe headache. It boils at 132° (269°.6 F.) and crystallizes at  $-20^\circ$  (4° F.); sp. gr. 0.8184 at 15° (5° F.). It mixes with alcohol and ether, but not with water. It burns difficultly with a pale blue flame.

When exposed to air it oxidizes very slowly; quite rapidly, however, in contact with platinum-black, forming valerianic acid. The same acid, along with other substances, is produced by the action of the more powerful oxidants upon amyl alcohol. Chlorin attacks it energetically, forming amyl chlorid,  $\text{HCl}$ , and other chlorinated derivatives. Sulphuric acid dissolves in amyl alcohol, with formation of amyl-sulphuric acid,  $\text{SO}_4(\text{C}_5\text{H}_{11})\text{H}$ , corresponding to ethyl-sulphuric acid. It also forms similar acids with phosphoric, oxalic, citric, and tartaric acids. Its ethers, when dissolved in ethyl alcohol, have the taste and odor of various fruits, and are used in the preparation of artificial fruit-essences. Amyl alcohol is also used in analysis as a solvent, particularly for certain alkaloids, and in pharmacy for the artificial production of valerianic acid and the valerianates.

**Diethyl carbinol—** $\begin{array}{c} \text{CH}_3\text{—CH}_2 \\ \text{CH}_3\text{—CH}_2 \end{array} \rangle \text{CHOH}$ —is produced by the action of a mixture of zinc and ethyl iodid on ethyl formiate, with the subsequent addition of  $\text{H}_2\text{O}$ . It is a liquid which boils at 116°.5 (241°.7 F.).

**Methyl-propyl-carbinol —** $\text{CH}_3\text{—CH}_2\text{—}\begin{array}{c} \text{CH}_2 \\ \text{CH}_2 \end{array} \rangle \text{CHOH}$ —a liquid, boiling at 118°.5 (245°.3 F.), obtained by the hydrogenation of methylpropylic acetone.

**Methyl-isopropyl-carbinol—Amylene hydrate—** $(\text{CH}_3)_2\text{—}\begin{array}{c} \text{CH} \\ \text{CH}_3 \end{array} \rangle \text{CHOH}$ —obtained by the hydrogenation of methyl-isopropylic acetone; or by the action of hydriodic acid upon amylenes, and the action of moist silver oxid upon the product so obtained. It is a colorless liquid, sp. gr. 0.829 at 0° (32° F.), having a pungent, ethereal odor; boils at 108° (226°.4 F.); soluble in  $\text{H}_2\text{O}$  and in alcohol. Has been used as a hypnotic.

**Ethyl-dimethyl-carbinol**—*Tertiary amylie alcohol*—

$\begin{array}{c} \text{CH}_3 \backslash \\ \text{CH}_3 - \text{CH}_3 - \text{COH} \\ \text{CH}_3 / \end{array}$ —is a liquid which solidifies at  $-12$  ( $10.4$  F.) and boils at  $102.5$  ( $216.5$  F.); formed by the action of zinc methyl upon propionyl chlorid, or by decomposition of tertiary sulphamylic acid by boiling  $\text{H}_2\text{O}$ . It is a colorless liquid; sp. gr.  $0.828$  at  $0^\circ$  ( $32$  F.), crystallizes at  $-30$  ( $-22$  F.), boils at about  $100$  ( $212$  F.). The nitrite of this alcohol has been used as a substitute for amyl nitrite.

**Cetyl hydrate**—*Cetylic alcohol*—*Ethal*— $\text{C}_{16}\text{H}_{33}\text{OH}$ —242—is obtained by the saponification of spermaceti (its palmitic ether). It is a white, crystalline solid; fusible at  $49$  ( $120.2$  F.); insoluble in  $\text{H}_2\text{O}$ ; soluble in alcohol and ether; tasteless and odorless.

**Ceryl hydrate**— $\text{C}_{17}\text{H}_{35}\text{OH}$ —396—and **Myricyl hydrate**— $\text{C}_{20}\text{H}_{41}\text{OH}$ —438—are obtained as white, crystalline solids: the former from China wax; the latter from beeswax, by saponification.

## SIMPLE ETHERS.

OXIDS OF ALCOHOLIC RADICALS OF THE SERIES  $\text{C}_n\text{H}_{2n+1}$ .

The term **ether** was originally applied to any volatile liquid obtained by the action of an acid upon an alcohol.

The simple ethers are the oxids of the alcoholic radicals. They bear the same relation to the alcohols that the oxids of the basylous elements bear to their hydrates:

When the two alcoholic radicals are the same, as in the above instance, the ether is designated as **simple**; when the radicals are different, as in methyl-ethyl oxid,  $\begin{array}{c} \text{CH}_3 \} \\ \text{C}_2\text{H}_5 \} \end{array} \text{O}$ , they are called **mixed ethers**.

**Methyl oxid**— $\begin{array}{c} \text{CH}_3 \} \\ \text{CH}_3 \} \end{array} \text{O}$ —46—isomeric with ethyl alcohol, is obtained by the action of  $\text{H}_2\text{SO}_4$  and boric acid upon methyl alcohol, or by the action of silver oxid on methyl iodid. It is a colorless gas; has an ethereal odor; burns with a pale flame; liquefies at  $-36$  ( $-32.8$  F.); and boils at  $-21$  ( $-5.8$  F.); is soluble in  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4$  and ethyl alcohol.

**Ethyl oxid**—**Ethylic ether**—**Ether**—**Sulphuric ether**—**Æther fortior** (U. S.)—**Æther purus** (Br.)— $\begin{array}{c} \text{C}_2\text{H}_5 \} \\ \text{C}_2\text{H}_5 \} \end{array} \text{O}$ —74.

**Preparation.**—A mixture is made of 5 pts. of alcohol, 90%, and 9

pts. of concentrated  $\text{H}_2\text{SO}_4$ , in a vessel surrounded by cold  $\text{H}_2\text{O}$ . This mixture is introduced into a retort, over which is a vessel from which a slow stream of alcohol is made to enter the retort. Heat is applied, and the addition of alcohol and the heat are so regulated that the temperature does not rise above  $140^\circ$  ( $284^\circ \text{F.}$ ). The retort is connected with a well-cooled condenser, and the process continued until the temperature in the retort rises above the point indicated. It is important that the tube by which the alcohol is introduced be drawn out to a small opening, and dip well down below the surface of the liquid. The distillate thus obtained contains ether, alcohol, water, and gases resulting from the decomposition of the alcohol and  $\text{H}_2\text{SO}_4$ , notably  $\text{SO}_2$ . It is subjected to a first purification by shaking with  $\text{H}_2\text{O}$  containing potash or lime, decanting the supernatant ether and redistilling. The product of this process is "washed ether," or *æther* (**U. S.**). It is still contaminated with water and alcohol, and when desired pure, as for producing anæsthesia and for processes of analysis, it is subjected to a second purification. It is again shaken with  $\text{H}_2\text{O}$ , decanted after separation, shaken with recently fused calcium chlorid and newly burnt lime, with which it is left in contact 24 hours, and from which it is then distilled.

It was known at an early day that a small quantity of  $\text{H}_2\text{SO}_4$  is capable of converting a large quantity of alcohol into ether, and that at the end of the process the  $\text{H}_2\text{SO}_4$  remains in the retort unaltered, except by secondary reactions. A metaphysical explanation of the process was found in the assertion that the acid acted by its mere presence, by *catalysis*, as it was said. In other words, it acts because it acts, a very ready but a very feminine method of explaining what is not understood, which is still invoked by some authors as a covering for our ignorance of the rationale of certain chemico-physiological phenomena. It was only in 1850 that Alex. Williamson, by a series of ingenious experiments, determined the true nature of the process. In the conversion of alcohol into ether, an intermediate substance, sulphovinic acid, is alternately formed at the expense of the alcohol, and destroyed with formation of ether and regeneration of  $\text{H}_2\text{SO}_4$ . At first  $\text{H}_2\text{SO}_4$  and alcohol act upon each other, molecule for molecule, to form  $\text{H}_2\text{O}$  and sulphovinic acid:  $\text{C}_2\text{H}_5 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O} + \text{H}_2 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O}_2$

$= \text{H} \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O} + \text{C}_2\text{H}_5 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O}_2$ . The new acid as soon as formed reacts with

a second molecule of alcohol, with regeneration of  $\text{H}_2\text{SO}_4$  and formation of ether:  $\text{C}_2\text{H}_5 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O}_2 + \text{C}_2\text{H}_5 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O} = \text{H}_2 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O}_2 + \text{C}_2\text{H}_5 \left\{ \begin{smallmatrix} \text{SO}_2 \\ \text{H} \end{smallmatrix} \right\} \text{O}$ .

Theoretically, therefore, a given quantity of  $\text{H}_2\text{SO}_4$  could con-

vert an unlimited amount of alcohol into ether. Such would also be the case in practice, were it not that the acid gradually becomes too dilute, by admixture with the  $H_2O$  formed during the reaction, and at the same time is decomposed by secondary reactions, into which it enters with impurities in the alcohol; causes which in practice limit the amount of ether produced to about four to five times the bulk of acid used.

Ether is a colorless, limpid, mobile, highly refracting liquid; it has a sharp, burning taste, and a peculiar, tenacious odor, characterized as ethereal. Sp. gr. 0.723 at 12.5 (54.5 F.); it boils at 34.5 (94.1 F.), and crystallizes at  $-31^{\circ}$  ( $-23^{\circ}.8$  F.). Its tension of vapor is very great, especially at high temperatures; it should, therefore, be stored in strong bottles, and should be kept in situations protected from elevations of temperature. It is exceedingly volatile, and, when allowed to evaporate freely, absorbs a great amount of heat, of which property advantage is taken to produce local anæsthesia, the part being benumbed by the cold produced by the rapid evaporation of ether sprayed upon the surface. Water dissolves one-ninth its weight of ether. Ethylic and methylic alcohols are miscible with it in all proportions. Ether is an excellent solvent of many substances not soluble in water and alcohol, while, on the other hand, it does not dissolve many substances soluble in those fluids. The resins and fats are readily soluble in ether; the salts of the alkaloids and many vegetable coloring matters are soluble in alcohol and water, but insoluble in ether, while the free alkaloids are for the most part soluble in ether, but insoluble, or very sparingly soluble, in water.

Ether, whether in the form of vapor or of liquid, is highly inflammable; and burns with a luminous flame. The vapor forms with air a violently explosive mixture. It is denser than air, through which it falls and diffuses itself to a great distance; great caution is therefore required in handling ether in a locality in which there is a light or fire, especially if the fire be near the floor.

Pure ether is neutral in reaction, but, on exposure to air or  $O$ , especially in the light, it becomes acid from the formation of a small quantity of acetic acid.  $H_2SO_4$  mixes with ether, with elevation of temperature, and formation of sulphovinic acid. Sulphuric anhydrid forms ethyl sulphate.  $HNO_3$ , aided by heat, oxidizes ether to carbon dioxid and acetic and oxalic acids. Ether, saturated with  $HCl$  and distilled, yields ethyl chlorid.  $Cl$ , in the presence of  $H_2O$ , oxidizes ether, with formation of aldehyde, acetic acid, and chloral. In the absence of  $H_2O$ , however, a series of products of substitution are produced, in which 2, 4 and 10 atoms of  $H$  are replaced by a corresponding number of atoms of  $Cl$ . These substances in turn, by substitution of alcoholic radicals, or

of atoms of elements, for atoms of Cl, give rise to other derivatives.

**Action on the Economy.**—Ether is largely used in medicine for producing anæsthesia, either locally by diminution of temperature due to its rapid evaporation, or generally by inhalation. When taken in overdose it causes death, although it is by no means as liable to give rise to fatal accidents as is chloroform. Patients suffering from an overdose may, in the vast majority of cases, be resuscitated by artificial respiration and the induced current, one pole to be applied to the nape of the neck, and the other carried across the body just below the anterior attachments of the diaphragm.

In cases of death from ether the odor is generally well marked in the clothing and surroundings, and especially on opening the thoracic cavity. In the analysis it is sought for in the blood and lungs at the same time as chloroform (q.v.).

### MONOBASIC ACIDS.

#### SERIES $C_nH_{2n}O_2$ .

As the higher terms of this series are obtained from the fats, and the lower terms are volatile liquids, these acids are sometimes designated as the **volatile fatty acids**.

Although formed in a variety of ways, these acids may be considered as being derived from the primary monoatomic alcohols, by the substitution of O for  $H_2$  in the group  $CH_2OH$ :

Considered typically, the substitution of O for  $H_2$  occurs in the radical:  $\begin{matrix} C_5H_{11} \\ H \end{matrix} \bigg\} O - \begin{matrix} C_5H_9O \\ H \end{matrix} \bigg\} O$ , and communicates to the radical electro-negative or acid qualities.

**Formic acid— $HCO,OH$ —46**—occurs in the acid secretion of red ants, in the stinging hairs of certain insects, in the blood, urine, bile, perspiration, and muscular fluid of man, in the stinging-nettle, and in the leaves of trees of the pine family. It is produced in a number of reactions: by the oxidation of many organic substances: sugar, starch, fibrin, gelatin, albumin, etc.; by the action of potash upon chloroform and kindred bodies; by the action of mineral acids in hydrocyanic acid; during the fermentation of diabetic urine; by the direct union of carbon mon-

oxid and water; by the decomposition of oxalic acid under the influence of glycerin at about  $100^{\circ}$  ( $212^{\circ}$  F.).

It is a colorless liquid, having an acid taste and a penetrating odor; it acts as a vesicant; it boils at  $100^{\circ}$  ( $212^{\circ}$  F.), and, when pure, crystallizes at  $0^{\circ}$  ( $32^{\circ}$  F.). It is miscible with  $H_2O$  in all proportions.

The mineral acids decompose it into  $H_2O$  and carbon monoxid. Oxidizing agents convert it into  $H_2O$  and carbon dioxid. Alkaline hydrates decompose it with formation of a carbonate and liberation of H. It acts as a reducing agent with the salts of the noble metals.

**Acetic acid**—*Acetyl hydrate*—*Hydrogen acetate*—*Pyroligneous acid*—**Acidum aceticum** (U. S. ; Br.)— $CH_3.COOH$ —60.

It is formed—(1.) By the oxidation of alcohol:

(2.) By the dry distillation of wood.

(3.) By the decomposition of natural acetates by mineral acids.

(4.) By the action of potash in fusion on sugar, starch, oxalic, tartaric, citric acids, etc.

(5.) By the decomposition of gelatin, fibrin, casein, etc., by  $H_2SO_4$  and manganese dioxid.

(6.) By the action of carbon dioxid upon sodium methyl:  $CO_2 + NaCH_3 = C_2H_5O_2Na$ ; and decomposition of the sodium acetate so produced.

The acetic acid used in the arts and in pharmacy is prepared by the destructive distillation of wood. The products of the distillation, which vary with the nature of the wood used, are numerous. Charcoal remains in the retort, while the distilled product consists of an acid, watery liquid; a tarry material; and gaseous products. The gases are carbon dioxid, carbon monoxid, and hydrocarbons. The tar is a mixture of empyreumatic oils, hydrocarbons, phenol, oxyphenol, acetic acid, ammonium acetate, etc.

The acid water is very complex, and contains, besides acetic acid, formic, propionic, butyric, valerianic, and oxyphenic acids, acetone, naphthalene, benzene, toluene, cumene, creasote, methyl alcohol, and methyl acetate, etc. Partially freed from tar by decantation, it still contains about 20 per cent. of tarry and oily material, and about 4 per cent. of acetic acid; this is the crude **pyroligneous acid of commerce**.

The crude product is subjected to a first purification by distillation: the first portions are collected separately and yield methyl alcohol (q.v.); the remainder of the distillate is the *distilled pyroligneous acid*, used to a limited extent as an antiseptic, but principally for the manufacture of acetic acid and the acetates.

It can only be freed from the impurities which it still contains by chemical means. To this end slacked lime and chalk are added, at a gentle heat, to neutralization; the liquid is boiled and allowed to settle twenty-four hours; the clear liquid, which is a solution of calcium acetate, is decanted and evaporated; the calcium salt is converted into sodium acetate, which is then purified by calcination at a temperature below 330° (626° F.), dissolved, filtered, and recrystallized; the salt is then decomposed by a proper quantity of  $\text{H}_2\text{SO}_4$ , and the liberated acetic acid separated by distillation.

The product so obtained is a solution of acetic acid in water, containing 36 per cent. of true acetic acid, and being of sp. gr. 1.047, U. S. (the acid of the Br. Ph. is weaker—33 per cent.  $\text{C}_2\text{H}_4\text{O}_2$ , and sp. gr. 1.044).

Pure acetic acid, known as **glacial acetic acid**, **acidum aceticum glaciale** (U. S.), is obtained by decomposition of a pure dry acetate by heat.

Acetic acid is a colorless liquid. Below 17° (62.6° F.), when pure, it is a crystalline solid. It boils at 119° (246.2° F.); sp. gr. 1.0801 at 0° (32° F.); its odor is penetrating and acid; in contact with the skin it destroys the epidermis and causes vesication; it mixes with  $\text{H}_2\text{O}$  in all proportions, the mixtures being less in volume than the sum of the volumes of the constituents. The sp. gr. of the mixtures gradually increase up to that containing 23 per cent. of  $\text{H}_2\text{O}$ , after which they again diminish, and all the mixtures containing more than 43 per cent. of acid are of higher sp. gr. than the acid itself.

Vapor of acetic acid burns with a pale blue flame; and is decomposed at a red heat. It only decomposes calcic carbonate in the presence of  $\text{H}_2\text{O}$ . Hot  $\text{H}_2\text{SO}_4$  decomposes and blackens it,  $\text{SO}_2$  and  $\text{CO}_2$  being given off. Under ordinary circumstances Cl acts upon it slowly, more actively under the influence of sunlight, to produce monochloroacetic acid,  $\text{CH}_2\text{ClCO}_2\text{H}$ ; dichloroacetic acid,  $\text{CHCl}_2\text{CO}_2\text{H}$ ; and trichloroacetic acid,  $\text{CCl}_3\text{CO}_2\text{H}$ . The last named is an odorless, acid, strongly vesicant, crystalline solid; fuses at 46° (114.8° F.) and boils at 195°–200° (383–392° F.).

**Analytical Characters.**—(1.) Warmed with  $\text{H}_2\text{SO}_4$  it blackens. (2.) With silver nitrate a white crystalline ppt., partly dissolved by heat; no reduction of Ag on boiling. (3.) Heated with  $\text{H}_2\text{SO}_4$  and  $\text{C}_2\text{H}_5\text{O}$ , acetic ether, recognizable by its odor, is given off. (4.) When an acetate is calcined with a small quantity of  $\text{As}_2\text{O}_3$  the foul odor of cacodyl oxid is developed. (5.) Neutral solution of ferric chlorid produces in neutral solutions of acetates a deep red color, which turns yellow on addition of free acid.

**Vinegar** is an acid liquid owing its acidity to acetic acid, and holding certain fixed and volatile substances in solution. It is

obtained from some liquid containing 10 per cent. or less of alcohol, which is converted into acetic acid by the transferring of atmospheric oxygen to the alcohol during the process of nutrition of a peculiar vegetable ferment, known as *mycoderma aceti*, or, popularly, as *mother of vinegar*. Vinegar is now manufactured principally by one of two processes—the German method, and that of Pasteur. In the former, the alcoholic fluid, which must also contain albuminous matter, is allowed to trickle slowly through barrels containing beech-wood shavings, supported by a perforated false bottom. By a suitable arrangement of holes and tubes, an ascending current of air is made to pass through the barrel. The acetic ferment clings to the shavings, and under its influence acetification takes place rapidly, owing to the large surface exposed to the air. In Pasteur's process, the ferment is sown upon the surface of the alcoholic liquid, contained in large, shallow, covered vats, from which the vinegar is drawn off after acetification has been completed; the mother is collected, washed, and used in a subsequent operation.

The liquids from which vinegar is made are wine, cider, and beer, to which dilute alcohol is frequently added; the most esteemed being that obtained from white wine. *Wine vinegar* has a pleasant, acid taste and odor; it consists of water, acetic acid (about 5 per cent.), potassium bitartrate, alcohol, acetic ether, glucose, malic acid, mineral salts present in wine, a fermentescible, nitrogenized substance, coloring matter, etc. Sp. gr. 1.020 to 1.025. When evaporated, it yields from 1.7 to 2.4 per cent. of solid residue.

Vinegars made from alcoholic liquids other than wine contain no potassium bitartrate, contain less acetic acid, and have not the aromatic odor of wine vinegar. *Cider vinegar* is of sp. gr. 1.020; is yellowish, has an odor of apples, and yields 1.5 per cent. of extract on evaporation. *Beer vinegar* is of sp. gr. 1.032; has a bitterish flavor, and an odor of sour beer; it leaves 6 per cent. of extract on evaporation.

The principal *adulterations* of vinegar are: *Sulphuric acid*, which produces a black or brown color when a few drops of the vinegar and some fragments of cane-sugar are evaporated over the water-bath to dryness. *Water*, an excess of which is indicated by a low power of saturation of the vinegar, in the absence of mineral acids. Two parts of good wine vinegar neutralize 10 parts of sodium carbonate; the same quantity of cider vinegar, 2.5 parts; and of beer vinegar, 2.5 parts of carbonate. *Pyroligneous acid* may be detected by the creasote-like odor and taste. *Pepper*, *capsicum*, and other acrid substances, are often added to communicate fictitious strength. In vinegar so adulterated an acrid odor is perceptible after neutralization of the acid with

sodium carbonate. *Copper, zinc, lead, and tin* frequently occur in vinegar which has been in contact with those elements, either during the process of manufacture or subsequently.

**Distilled vinegar** is prepared by distilling vinegar in glass vessels; it contains none of the fixed ingredients of vinegar, but its volatile constituents (acetic acid, water, alcohol, acetic ether, odorous principles, etc.), and a small quantity of aldehyde.

When dry acetate of copper is distilled, a blue, strongly acid liquid passes over; this, upon rectification, yields a colorless, mobile liquid, which boils at  $56^{\circ}$  ( $132.8^{\circ}$  F.), has a peculiar odor, and is a mixture of acetic acid, water, and acetone, known as **radical vinegar**.

**Toxicology.**—When taken internally, acetic acid and vinegar (the latter in doses of 4–5 fl.  $\frac{z}{j}$ ) act as irritants and corrosives, causing in some instances perforation of the stomach, and death in 6–15 hours. Milk of magnesia should be given as an antidote, with the view to neutralizing the acid.

**Propionic acid**— $\text{CH}_3\text{CH}_2\text{COOH}$ —is formed by the action of caustic potassa upon sugar, starch, gum, and ethyl cyanid; during fermentation, vinous or acetic; in the distillation of wood; during the putrefaction of peas, beans, etc.; by the oxidation of normal propylic alcohol, etc. It is best prepared by heating ethyl cyanid with potash until the odor of the ether has disappeared; the acid is then liberated from its potassium compound by  $\text{H}_2\text{SO}_4$  and purified.

It is a colorless liquid, sp. gr. 0.996, does not solidify at  $-21^{\circ}$  ( $-5.8^{\circ}$  F.), boils at  $140^{\circ}$  ( $284^{\circ}$  F.), mixes with water and alcohol in all proportions, resembles acetic acid in odor and taste. Its salts are soluble and crystallizable.

**Butyric acid**—**Propyl-formic acid**— $\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$ —has been found in the milk, perspiration, muscular fluid, the juices of the spleen and of other glands, the urine, contents of the stomach and large intestine, feces, and guano; in certain fruits, in yeast, in the products of decomposition of many vegetable substances; and in natural waters; in fresh butter in small quantity, more abundantly in that which is rancid.

It is formed by the action of  $\text{H}_2\text{SO}_4$  and manganese dioxid, aided by heat, upon cheese, starch, gelatin, etc.; during the combustion of tobacco (as ammonium butyrate); by the action of  $\text{HNO}_3$  upon oleic acid; during the putrefaction of fibrin and other albuminoids; during a peculiar fermentation of glucose and starchy material in the presence of casein or gluten. This fermentation, known as the butyric, takes place in two stages: at first the glucose is converted into lactic acid:  $\text{C}_6\text{H}_{12}\text{O}_6 = 2(\text{C}_3\text{H}_6\text{O}_3)$ ; and this in turn is decomposed into butyric acid, carbon dioxid, and hydrogen:  $2\text{C}_3\text{H}_6\text{O}_3 = \text{C}_4\text{H}_8\text{O}_2 + 2\text{CO}_2 + 2\text{H}_2$ .

Butyric acid is obtained from the animal charcoal which has been used in the purification of glycerin, in which it exists as calcium butyrate. It is also formed by subjecting to fermentation a mixture composed of glucose, water, chalk, and cheese or gluten. The calcium butyrate is decomposed by  $\text{H}_2\text{SO}_4$ , and the butyric acid separated by distillation.

Butyric acid is a colorless, mobile liquid, having a disagreeable, persistent odor of rancid butter, and a sharp, acid taste; soluble in water, alcohol, ether, and methyl alcohol; boils at  $164$  ( $327.2$  F.), distilling unchanged; solidifies in a mixture of solid carbon dioxide and ether; sp. gr.  $0.974$  at  $15$  ( $59$  F.); a good solvent of fats.

It is not acted upon by  $\text{H}_2\text{SO}_4$  in the cold, and only slightly under the influence of heat. Nitric acid dissolves it unaltered in the cold, but on the application of heat, oxidizes it to succinic acid. Dry Cl under the influence of sunlight, and Br under the influence of heat and pressure, form products of substitution with butyric acid. It readily forms ethers and salts.

Butyric acid is formed in the intestine, by the process of fermentation mentioned above, at the expense of those portions of the carbohydrate elements of food which escape absorption, and is discharged with the feces as ammonium butyrate.

**Isobutyric acid—Isopropyl-formic acid**— $\begin{matrix} \text{CH}_3 \\ \diagup \\ \text{CH} \\ \diagdown \\ \text{CH}_3 \end{matrix}$ — $\text{COOH}$ —boils at  $152$  ( $305.6$  F.), has been found in human feces. It corresponds to isobutyl alcohol, from which it is produced by oxidation.

**Valerianic acids**— $\text{C}_5\text{H}_{10}\text{CO}_2\text{OH}$ — $102$ .—Corresponding to the four primary amyl alcohols, there are four possible amyl or valerianic acids, of which three, I., II., and IV., are known.

**I. Normal valerianic acid—Butylformic acid—Propylacetic acid**—is obtained by the oxidation of normal amyl alcohol. It is an oily liquid, boils at  $185$  ( $365$  F.), and has an odor resembling that of butyric acid.

**II. Ordinary valerianic acid—Delphinic acid—Phoenic acid—Isovaleric acid—Isopropyl acetic acid—Isobutylformic acid—Acidum valerianicum (Br.).**—This acid exists in the oil of the porpoise, and in valerian root and in angelica root. It is formed during putrid fermentation or oxidation of albuminoid substances. It occurs in the urine and feces in typhus, variola, and

acute atrophy of the liver. It is also formed in a variety of chemical reactions, and notably by the oxidation of amyllic alcohol.

It is prepared either by distilling water from valerian root, or, more economically, by mixing rectified amyllic alcohol with  $\text{H}_2\text{SO}_4$ , adding when cold, a solution of potassium dichromate, and distilling after the reaction has become moderated: the distillate is neutralized with sodium carbonate; and the acid is obtained from the sodium valerianate so produced, by decomposition by  $\text{H}_2\text{SO}_4$  and rectification.

The ordinary valerianic acid is an oily, colorless liquid, having a penetrating odor, and a sharp, acrid taste. It solidifies at  $-16$  ( $3.2$  F.); boils at  $173-175$  ( $343.4-347$  F.); sp. gr.  $0.9343-0.9465$  at  $20^\circ$  ( $68$  F.); burns with a white, smoky flame. It dissolves in 30 parts of water, and in alcohol and ether in all proportions. It dissolves phosphorus, camphor, and certain resins.

IV. Trimethyl acetic acid—*Pivalic acid*—is a crystalline solid, which fuses at  $35.5$  ( $96$  F.) and boils at  $163.7$  ( $326.7$  F.); sparingly soluble in  $\text{H}_2\text{O}$ ; obtained by the action of cyanid of mercury upon tertiary butyl iodid.

Caproic acids—*Hexylic acids*— $\text{C}_6\text{H}_{11}\text{COOH}$ —116.—There probably exist quite a number of isomeres having the composition indicated above, some of which have been prepared from butter, cocoa-oil, and cheese, and by decomposition of amyl cyanid, or of hexyl alcohol.

The acid obtained from butter, in which it exists as a glyceric ether, is a colorless, oily liquid, boils at  $205$  ( $401$  F.); sp. gr.  $0.931$  at  $15$  ( $59$  F.); has an odor of perspiration and a sharp, acid taste; is very sparingly soluble in water, but soluble in alcohol.

Enanthylic acid—*Heptylic acid*— $\text{C}_7\text{H}_{13}\text{COOH}$ —130—exists in spirits distilled from rice and maize, and is formed by the action of  $\text{HNO}_3$  on fatty substances, especially castor-oil. It is a colorless oil; sp. gr.  $0.9167$ ; boils at  $212^\circ$  ( $413.6$  F.).

Caprylic acid—*Octylic acid*— $\text{C}_8\text{H}_{15}\text{COOH}$ —144—accompanies caproic acid in butter, cocoa-oil, etc. It is a solid; fuses at  $15$  ( $59$  F.); boils at  $236^\circ$  ( $457^\circ$  F.); almost insoluble in  $\text{H}_2\text{O}$ .

Pelargonic acid—*Nonylic acid*— $\text{C}_9\text{H}_{17}\text{COOH}$ —158.—A colorless oil, solid below  $10$  ( $50$  F.); boils at  $260$  ( $500$  F.); exists in oil of geranium, and is formed by the action of  $\text{HNO}_3$  on oil of rue.

Capric acid—*Decylic acid*— $\text{C}_{10}\text{H}_{19}\text{COOH}$ —172—exists in butter, cocoa-oil, etc., associated with caproic and caprylic acids in their glyceric ethers, and in the residues of distillation of Scotch whiskey, as amyl caprate. It is a white, crystalline solid; melts at  $27.5$  ( $81.5$  F.); boils at  $273^\circ$  ( $523.4$  F.).

Lauric acid—*Laurostearic acid*— $\text{C}_{11}\text{H}_{21}\text{COOH}$ —200—is a solid, fusible at  $43.5$  ( $110.3$  F.), obtained from laurel berries, cocoa-butter, and other vegetable fats.

**Myristic acid**— $C_{13}H_{27}COOH$ —228.—A crystalline solid, fusible at  $54^{\circ}$  ( $129.2^{\circ} F.$ ); existing in many vegetable oils, cow's butter, and spermaceti.

**Palmitic acid**—*Ethalic acid*— $C_{15}H_{31}COOH$ —256—exists in palm-oil, in combination when the oil is fresh, and free when the oil is old; it also enters into the composition of nearly all animal and vegetable fats. It is obtained from the fats, palm-oil, etc., by saponification with caustic potassa and subsequent decomposition of the soap by a strong acid. It is also formed by the action of caustic potash in fusion upon cetyl alcohol (ethal), and by the action of the same reagent upon oleic acid.

Palmitic acid is a white, crystalline solid; odorless, tasteless; lighter than  $H_2O$ , in which it is insoluble; quite soluble in alcohol and in ether; fuses at  $62^{\circ}$  ( $143.6^{\circ} F.$ ); distils unchanged with vapor of water.

**Margaric acid**— $C_{17}H_{33}COOH$ —270—formerly supposed to exist as a glycerid in all fats, solid and liquid. What had been taken for margaric acid was a mixture of 90 per cent. of palmitic and 10 per cent. of stearic acid. It is obtained by the action of potassium hydrate upon cetyl cyanid, as a white, crystalline body; fusible at  $59^{\circ}.9$  ( $140^{\circ} F.$ ).

**Stearic acid**— $C_{18}H_{35}COOH$ —284—exists as a glycerid in all solid fats, and in many oils, and also free to a limited extent.

To obtain it pure, the fat is saponified with an alkali, and the soap decomposed by  $HCl$ ; the mixture of fatty acids is dissolved in a large quantity of alcohol, and the boiling solution *partly* precipitated by the addition of a concentrated solution of barium acetate. The precipitate is collected, washed, and decomposed by  $HCl$ ; the stearic acid which separates is washed and recrystallized from alcohol. The process is repeated until the product fuses at  $70^{\circ}$  ( $158^{\circ} F.$ ). Stearic acid is formed from oleic acid (q.v.) by the action of iodine under pressure at  $270^{\circ}$ – $280^{\circ}$  ( $518^{\circ}$ – $536^{\circ} F.$ ).

Pure stearic acid is a colorless, odorless, tasteless solid; fusible at  $70^{\circ}$  ( $158^{\circ} F.$ ); unctuous to the touch; insoluble in  $H_2O$ ; very soluble in alcohol and in ether. The alkaline stearates are soluble in  $H_2O$ ; those of  $Ca$ ,  $Ba$ , and  $Pb$  are insoluble.

Stearic and palmitic acids exist free in the intestine during the digestion of fats, a portion of which is decomposed by the action of the pancreatic secretion into fatty acids and glycerin. The same decomposition also occurs in the presence of putrefying albuminoid substances.

**Arachic acid**— $C_{19}H_{39}COOH$ —312—exists as a glycerid in peanut-oil (now largely used as a substitute for olive-oil), in oil of ben, and in small quantity in butter. It is a crystalline solid, which melts at  $75^{\circ}$  ( $167^{\circ} F.$ ).

## COMPOUND ETHERS.

As the alcohols resemble the mineral bases, and the organic acids resemble those of mineral origin, so the compound ethers are similar in constitution to the salts, being *formed by the double decomposition of an alcohol with an acid, mineral or organic*, as a salt is formed by double decomposition of an acid and a mineral base, the radical playing the part of an atom of corresponding valence :

Therefore the compound ethers are acids whose hydrogen has been partially or completely displaced by a hydrocarbon radical or radicals.

Some of the compound ethers still contain a portion of the acid hydrogen which, being replaceable by another radical or by a metal, communicates acid qualities to the substance, which is at the same time a compound ether and a true acid.

The compound ethers are produced :

1.) By the action of the acid upon the alcohol :

2.) By the action of the corresponding haloid ethers upon the silver salt of the acid :

3.) By the action of the chlorids of the acid radicals upon the sodium derivatives of the alcohols, and in some instances upon the alcohols themselves :

All compound ethers are decomposed into acid and alcohol by the action of water at high temperatures, or of caustic potash or soda :

As this decomposition is analogous to that utilized in the manufacture of soap (q. v.), it is known as **saponification**, and whenever an ether is so decomposed it is said to be **saponified**.

**Methyl nitrate**— $\left. \begin{smallmatrix} \text{NO}_2 \\ \text{CH}_3 \end{smallmatrix} \right\} \text{O}$ —77.—A colorless liquid; sp. gr. 1.182 at 22° (71.6 F.); boils at 66° (150.8 F.); gives off vapor which detonates at 150° (302 F.). Prepared by the action of potassium nitrate and  $\text{H}_2\text{SO}_4$  on methyl alcohol.

**Methyl nitrite**— $\left. \begin{smallmatrix} \text{NO} \\ \text{CH}_3 \end{smallmatrix} \right\} \text{O}$ —61—obtained by heating methyl alcohol with  $\text{HNO}_3$  and Cu. Below  $-12^\circ$  (10.4 F.) it is a yellowish liquid; above that temperature a gas.

**Ethyl nitrate**—*Nitric ether*— $\left. \begin{smallmatrix} \text{NO}_2 \\ \text{C}_2\text{H}_5 \end{smallmatrix} \right\} \text{O}$ —91.—A colorless liquid; has a sweet taste and bitter after-taste; sp. gr. 1.112 at 17° (62.6 F.); boils at 85° (185 F.); gives off explosive vapors. Prepared by distilling a mixture of  $\text{HNO}_3$  and  $\text{C}_2\text{H}_5\text{O}$  in the presence of urea.

**Ethyl nitrite**—*Nitrous ether*— $\left. \begin{smallmatrix} \text{NO} \\ \text{C}_2\text{H}_5 \end{smallmatrix} \right\} \text{O}$ —75—is best prepared by directing the nitrous fumes, produced by the action of starch on  $\text{HNO}_2$  under the influence of heat, into alcohol, contained in a retort connected with a well-cooled receiver.

It is a yellowish liquid; has an apple-like odor, and a sharp, sweetish taste; sp. gr. 0.947; boils at 18° (64.4 F.); gives off inflammable vapor; very sparingly soluble in  $\text{H}_2\text{O}$ ; readily soluble in alcohol and ether.

Warm  $\text{H}_2\text{O}$  decomposes it into  $\text{C}_2\text{H}_5\text{O}$ ,  $\text{HNO}_3$  and NO. Alkalies decompose it into malate and nitrate of the alkaline element. It is energetically attacked by  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{S}$  and the alkaline sulphids. It is liable to spontaneous decomposition, especially in the presence of  $\text{H}_2\text{O}$ .

Its vapor rapidly produces anæsthesia; it is, however, used only in alcoholic solution: **Spiritus ætheris nitrosi** (U. S., Br.), which also contains aldehyde. Owing to the presence of the last-named substance, and to the presence of  $\text{H}_2\text{O}$ , the spirit is very liable to become acid, either from the formation of acetic acid by the oxidation of the aldehyde, or from the decomposition of the ether under the influence of  $\text{H}_2\text{O}$ , a change which renders it unfit for use in many of the prescriptions in which it is frequently used, especially in that with potassium iodid, from which it liberates iodine. The presence of free acid may be detected by effervescence when the spirit is shaken with hydrosodic carbonate. Its acidity may be corrected by shaking with potassium carbonate, and decanting, provided it does not contain  $\text{H}_2\text{O}$ . (See Nitro-paraffins.)

**Ethyl sulphates.**—These are two in number :  $(C_2H_5)HSO_4 =$  Ethyl-sulphuric or sulphovinic acid and  $(C_2H_5)_2SO_4$ —Ethyl sulphate—Sulphuric ether.

**Ethyl-sulphuric Acid**— $(C_2H_5) \begin{matrix} SO_2 \\ H \end{matrix} \left\{ \begin{matrix} O_2-126 \end{matrix} \right.$ —is formed as an intermediate product in the manufacture of ethylic ether (q. v.).

Pure ethyl-sulphuric acid is a colorless, syrupy, highly acid liquid ; sp. gr. 1.316 ; soluble in water and alcohol in all proportions, insoluble in ether.

It decomposes slowly at ordinary temperatures, more rapidly when heated. When heated alone or with alcohol, it yields ether and  $H_2SO_4$ . When heated with  $H_2O$ , it yields alcohol and  $H_2SO_4$ . It forms crystalline salts, known as **sulphovinates**, one of which, **sodium sulphovinate**,  $(C_2H_5)NaSO_4$ , has been used in medicine. It is a white, deliquescent solid either crystalline with 1 Aq, or granular and anhydrous ; soluble in  $H_2O$ . Its solution should give no precipitate with barium chlorid.

**Ethyl Sulphate**,— $(C_2H_5)_2SO_4$ —154—the true sulphuric ether, is obtained by passing vapor of  $SO_3$  into *pure* ethylic ether, thoroughly cooled.

It is a colorless, oily liquid ; has a sharp, burning taste, and the odor of peppermint ; sp. gr. 1.120 ; it cannot be distilled without decomposition ; in contact with  $HO_2$  it is decomposed with formation of sulphovinic acid.

By the action of an excess of  $H_2SO_4$  upon alcohol ; by the dry distillation of the sulphovinates ; and in the last stages of manufacture of ether, a yellowish, oily liquid, having a penetrating odor, and a sharp, bitter taste, is formed. This is **sweet or heavy oil of wine**, and its ethereal solution is **Oleum æthereum (U. S.)**. It seems to be a mixture of ethyl sulphate with hydrocarbons of the series  $C_nH_{2n}$ . On contact with  $H_2O$  or an alkaline solution, it is decomposed, sulphovinic acid is formed, and there separates a colorless oil, of sp. gr. 0.917, boiling at  $280$  ( $536$  F.), which is **light oil of wine**. This oil is polymeric with ethylene, and is probably cetene,  $C_{16}H_{32}$ . It is sometimes called **etherin** or **etherol**.

**Sulphurous and Hyposulphurous ethers.**—These compounds have recently assumed medical interest from their relationship to mercaptan, sulphonal and a number of aromatic derivatives used as medicines.

There exist two isomeric sulphurous acids (see p. 97), both of which yield neutral ethers, but only one of which, the unsymmetrical,  $\begin{matrix} O \\ \parallel \\ O \end{matrix} \begin{matrix} \backslash H \\ \backslash OH \end{matrix}$ , forms acid ethers. These acid ethers are known as **sulphonic acids**. (See Aromatic sulphonic acids, mercaptan, sulphones, sulphonal.)

**Diethyl sulphite**— $(C_2H_5)_2SO_3$ —is produced by the action of

thionyl chlorid on absolute alcohol :  $\text{SOCl}_2 + 2\text{C}_2\text{H}_5\text{HO} = \text{SO}_2 + (\text{C}_2\text{H}_5)_2 + 2\text{HCl}$ . It is a colorless liquid, having a powerful odor : sp. gr. 1.085, boils at  $161^\circ$  ( $321.8^\circ \text{F.}$ ).  $\text{H}_2\text{O}$  decomposes it into alcohol and sulphurous acid.

**Ethyl sulphonic acid.**— $\text{SO}_2 \begin{smallmatrix} \diagup \text{C}_2\text{H}_5 \\ \diagdown \text{OH} \end{smallmatrix}$ —is formed by the action of ethyl iodid on potassium sulphite :  $\text{C}_2\text{H}_5\text{I} + \text{SO}_3\text{K}_2 = \text{C}_2\text{H}_5\text{SO}_3\text{OK} + \text{KI}$ . It forms salts and ethers.

**Sulphinic acids**—are the acid ethers of hyposulphurous acid  $\text{SO} \begin{smallmatrix} \diagup \text{H} \\ \diagdown \text{OH} \end{smallmatrix}$ , and are analagous to the sulphonic acids.

**Ethyl acetate—Acetic ether—Æther aceticus (U. S.)**— $\begin{smallmatrix} \text{C}_2\text{H}_5\text{O} \\ \text{C}_2\text{H}_5 \end{smallmatrix} \text{O}$ —88—is obtained by distilling a mixture of sodium acetate, alcohol and  $\text{H}_2\text{SO}_4$ ; or by passing carbon dioxid through an alcoholic solution of potassium acetate.

It is a colorless liquid, has an agreeable, ethereal odor; boils at  $74^\circ$  ( $165.2^\circ \text{F.}$ ); sp. gr. 0.89 at  $15^\circ$  ( $59^\circ \text{F.}$ ); soluble in 6 pts. water, and in all proportions in methyl and ethyl alcohols and in ether; a good solvent of essences, resins, cantharidin, morphin, gun-cotton, and in general, of substances soluble in ether; burns with a yellowish-white flame. Chlorin acts energetically upon it, producing products of substitution, varying according to the intensity of the light from  $\text{C}_4\text{H}_6\text{Cl}_2\text{O}_2$  to  $\text{C}_4\text{Cl}_2\text{O}_2$ .

**Amyl nitrate**— $\begin{smallmatrix} \text{NO}_2 \\ \text{C}_5\text{H}_{11} \end{smallmatrix} \text{O}$ —133—obtained by distilling a mixture of  $\text{HNO}_3$  and amylie alcohol in the presence of a small quantity of urea. It is a colorless, oily liquid; sp. gr. 0.994 at  $10^\circ$  ( $50^\circ \text{F.}$ ); boils at  $148^\circ$  ( $298.4^\circ \text{F.}$ ) with partial decomposition.

**Amyl nitrite—Amyl nitris (U. S.)**— $\begin{smallmatrix} \text{NO} \\ \text{C}_5\text{H}_{11} \end{smallmatrix} \text{O}$ —117—prepared by directing the nitrous fumes, evolved by the action of  $\text{HNO}_3$  upon starch, into amyl alcohol contained in a retort heated over a water-bath; purifying the distillate by washing with an alkaline solution and rectifying.

It is a slightly yellowish liquid; sp. gr. 0.877; boils at  $95^\circ$  ( $203^\circ \text{F.}$ ); its vapor explodes when heated to  $260^\circ$  ( $500^\circ \text{F.}$ ); insoluble in water; soluble in alcohol in all proportions; vapor orange-colored. Alcoholic solution of potash decomposes it slowly, with formation of potassium nitrite and oxids of ethyl and amyl. When dropped upon fused potash, it ignites and yields potassium valerianate.

Amyl nitrite is frequently impure; its boiling-point should not vary more than two or three degrees from that given above.

**Cetyl palmitate—Cetin**— $\begin{smallmatrix} \text{C}_{16}\text{H}_{31}\text{O} \\ \text{C}_{16}\text{H}_{33} \end{smallmatrix} \text{O}$ —480—is the chief constituent of spermaceti = cetaceum (U. S., Br.). This is the concrete portion, obtained by expression and crystallization from

alcohol, of the oil contained in the cranial sinuses of the sperm whale. It forms white, crystalline plates; fusible at  $49^{\circ}$  ( $120.2^{\circ}$  F.); slightly unctuous to the touch; tasteless, and almost odorless; insoluble in water; soluble in alcohol and ether; burns with a bright flame. Besides cetin, it contains ethers not only of palmitic, but also of stearic, myristic, and laurostearic acids; and of the alcohols: **lethal**,  $C_{12}H_{26}O$ ; **methal**,  $C_{14}H_{30}O$ ; **ethal**,  $C_{16}H_{34}O$ ; and **stethal**,  $C_{18}H_{38}O$ .

**Melissyl palmitate**—*Melissin*— $\left. \begin{matrix} C_{16}H_{31}O \\ C_{30}H_{61} \end{matrix} \right\} O$ —676.—Beeswax consists mainly of two substances; **cerotic acid**,  $C_{27}H_{53}O.OH$ , which is soluble in boiling alcohol, and **melissyl palmitate**, insoluble in that liquid, united with minute quantities of substances which communicate to the wax its color and odor. Yellow wax melts at  $62-63^{\circ}$  ( $143.6-145.4^{\circ}$  F.); after bleaching, which is brought about by exposure to light, air, and moisture, it does not fuse below  $66^{\circ}$  ( $150.8^{\circ}$  F.). **China wax**, a white substance resembling spermaceti, is a vegetable product, consisting chiefly of **ceryl cerotate**,  $C_{27}H_{53}O_2(C_{27}H_{55})$ .

## ALDEHYDES.

### SERIES $C_nH_{2n}O$ .

It will be remembered that the monobasic acids are obtained from the alcohols by oxidation of the radical:

These oxidized radicals are capable of forming compounds similar in constitution to those of the non-oxidized radicals. There are chlorids, bromids, and iodids: their hydrates are the acids,  $\left( \begin{matrix} C_2H_3O \\ H \end{matrix} \right) \left. \vphantom{\begin{matrix} C_2H_3O \\ H \end{matrix}} \right\} O$  = acetic acid; their oxids are known as **anhydrids**,  $\left( \begin{matrix} C_2H_3O \\ C_2H_3O \end{matrix} \right) \left. \vphantom{\begin{matrix} C_2H_3O \\ C_2H_3O \end{matrix}} \right\} O$  = acetic anhydrid; and their hydrids are the **aldehydes**,  $\left( \begin{matrix} C_2H_3O \\ H \end{matrix} \right) \left. \vphantom{\begin{matrix} C_2H_3O \\ H \end{matrix}} \right\} =$  acetic aldehyde. The name aldehyde is a corruption of **alcohol dehydrogenatum**, from the method of their formation, by the removal of hydrogen from alcohol.

The aldehydes all contain the group of atoms  $(COH)'$ , and their constitution may be thus graphically indicated:

They are capable, by fixing  $H_2$ , of regenerating the alcohol; and, by fixing  $O$ , of forming the corresponding acid:

The aldehydes combine with the acid sulphites of the alkali metals to form crystalline compounds. They combine with ammonia to form **aldehyde-ammonias**:  $\text{CH}_3\text{CHO} + \text{NH}_3 = \text{CH}_3\text{CH} \begin{smallmatrix} \text{OH} \\ \text{NH}_2 \end{smallmatrix}$ . They are converted by  $\text{Cl}$  and  $\text{Br}$  into the chlorids or bromids of the acid radicals.

The aldehydes are formed:

1.) By the limited oxidation of the corresponding alcohol:  $\text{CH}_3\text{CH}_2\text{OH} + \text{O} = \text{CH}_3\text{COH} + \text{H}_2\text{O}$ .

2.) By the action of nascent  $H$  upon the chlorids or anhydrids of the corresponding acids:  $\text{CH}_3\text{COCl} + \text{H}_2 = \text{CH}_3\text{COH} + \text{HCl}$  or  $(\text{CH}_3\text{CO})_2\text{O} + 2\text{H}_2 = 2\text{CH}_3\text{COH} + \text{H}_2\text{O}$ .

3.) By the distillation of a mixture of calcium formiate and the  $\text{Ca}$  salt of the corresponding acid:  $(\text{HCOO})_2\text{Ca} + (\text{CH}_3\text{COO})_2\text{Ca} = 2\text{CO}_2\text{Ca} + 2\text{CH}_3\text{COH}$ .

**Formaldehyde**—*Formyl hydrid*— $\text{H}\cdot\text{COH}$ —30—is formed when air charged with vapor of methylic alcohol is passed over an incandescent platinum wire. It is also produced by the dry distillation of calcium formiate:  $(\text{HCOO})_2\text{Ca} = \text{CaCO}_3 + \text{HCOH}$ . It has not been obtained pure, but is known in solution in methyl alcohol.

Corresponding to this aldehyde is a product of condensation.

**Paraformaldehyde**, or **Trioxymethane**  $(\text{H}\cdot\text{COH})_3$ , which is obtained, as a crystalline substance, fusing at  $152^\circ$  ( $305.6^\circ \text{F.}$ ), insoluble in  $\text{H}_2\text{O}$ , alcohol and ether, by distilling glycollic acid with  $\text{H}_2\text{SO}_4$ , or by the action of silver oxalate or oxid on methene iodid:  $3\text{CH}_2\text{I}_2 + 3\text{COOAg}_2 = (\text{HCOH})_3 + 6\text{AgI} + 3\text{CO}$ .

**Acetaldehyde**—**Acetic aldehyde**—*Acetyl hydrid*— $\text{CH}_3\text{COH}$ —44—is formed in all reactions in which alcohol is deprived of  $H$  without introduction of  $O$ . It is prepared by distilling from a capacious retort, connected with a well-cooled condenser, a mixture of  $\text{H}_2\text{SO}_4$ , 6 pts.;  $\text{H}_2\text{O}$ , 4 pts.; alcohol, 4 pts.; and powdered manganese dioxid, 6 pts. The product is redistilled from calcium chlorid below  $50^\circ$  ( $122^\circ \text{F.}$ ). The second distillate is mixed with two volumes of ether, cooled by a freezing mixture, and saturated with dry  $\text{NH}_3$ ; there separate crystals of **ammonium acetylid**,  $\text{C}_2\text{H}_3\text{O}$ ,  $\text{NH}_4$ , which are washed with ether, dried, and decomposed in a distilling apparatus, over the water-bath, with the proper quantity of dilute  $\text{H}_2\text{SO}_4$ ; the distillate is finally dried over calcium chlorid and rectified below  $35^\circ$  ( $95^\circ \text{F.}$ ).

Aldehyde is a colorless, mobile liquid; has a strong, suffocating odor; sp. gr. 0.790 at 18° (64.4 F.); boils at 21° (69.8 F.); soluble in all proportions in water, alcohol and ether. If perfectly pure, it may be kept unchanged; but if an excess of acid have been used in its preparation, it gradually decomposes. When heated to 100° (212 F.), it is decomposed into water and crotonic aldehyde.

In the presence of nascent H, aldehyde takes up  $H_2$  and regenerates alcohol. Cl converts it into acetyl chlorid,  $C_2H_3O$ , Cl, and other products. Oxidizing agents quickly convert it into acetic acid. At the ordinary temperature  $H_2SO_4$ ;  $HCl$ ; and  $SO_2$  convert it into a solid substance called paraldehyde,  $C_6H_{12}O_3$  (?), which fuses at 10.5° (50.9 F.); boils at 124° (255.2 F.), and is more soluble in cold than in warm water. When heated with potassium hydrate, aldehyde becomes brown, a brown resin separates, and the solution contains potassium formiate and acetate. If a watery solution of aldehyde be treated, first with  $NH_3$  and then with  $H_2S$ , a solid, crystalline base, thialdin,  $C_6H_{11}NS_2$ , separates. It also forms crystalline compounds with the alkaline bisulphites. It decomposes solutions of silver nitrate, separating the silver in the metallic form, and under conditions which cause it to adhere strongly to glass.

Vapor of aldehyde, when inhaled in a concentrated form, produces asphyxia, even in comparatively small quantity; when diluted with air it is said to act as an anæsthetic. When taken internally it causes sudden and deep intoxication, and it is to its presence that the first products of the distillation of spirits of inferior quality owe in a great measure their rapid, deleterious action.

**Trichloraldehyde** — *Trichloroacetyl hydrid* — **Chloral** —  $CCl_3COH$  — 147.5 — is one of the final products of the action of Cl upon alcohol, and is obtained by passing dry Cl through absolute alcohol to saturation; applying heat toward the end of the reaction, which requires several hours for its completion. The liquid separates into two layers; the lower is removed and shaken with an equal volume of concentrated  $H_2SO_4$ , and again allowed to separate into two layers; the upper is decanted; again mixed with  $H_2SO_4$ , from which it is distilled; the distillate is treated with quicklime, from which it is again distilled, that portion which passes over between 94° and 99° (201.2–210.2 F.) being collected. It sometimes happens that chloral in contact with  $H_2SO_4$  is converted into a modification, insoluble in  $H_2O$ , known as **metachloral**; when this occurs it is washed with  $H_2O$ , dried and heated to 180° (356 F.), when it is converted into the soluble variety, which distils over.

Chloral is a colorless liquid, unctuous to the touch; has a pene-

trating odor and an acrid, caustic taste; sp. gr. 1.502 at 18° (64.4 F.); boils at 94.4 (201.9 F.); very soluble in water, alcohol, and ether; dissolves Cl, Br, I, S and P. Its vapor is highly irritating. It distils without alteration.

Although chloral has not been obtained by the direct substitution of Cl for H in aldehyde, its reactions show it to be an aldehyde. It forms crystalline compounds with the bisulphites; it reduces solutions of silver nitrate in the presence of  $\text{NH}_3$ ;  $\text{NH}_3$  and  $\text{H}_2\text{S}$  form with it a compound similar to thialdin; with nascent H it regenerates aldehyde; oxidizing agents convert it into trichloroacetic acid. Alkaline solutions decompose it with formation of chloroform and a formiate.

With a small quantity of  $\text{H}_2\text{O}$  chloral forms a solid, crystalline hydrate, heat being at the same time liberated. This hydrate has the composition  $\text{C}_2\text{HCl}_3\text{O} \cdot \text{H}_2\text{O}$ , and its constitution, as well as that of chloral itself, is indicated by the formulæ:

**Chloral hydrate—Chloral (U. S.)**—is a white, crystalline solid; fuses at 57° (134.6 F.); boils at 98° (208.4 F.), at which temperature it suffers partial decomposition into chloral and  $\text{H}_2\text{O}$ ; volatilizes slowly at ordinary temperatures; is very soluble in  $\text{H}_2\text{O}$ ; neutral in reaction; has an ethereal odor, and a sharp, pungent taste. Concentrated  $\text{H}_2\text{SO}_4$  decomposes it with formation of chloral and chloralid.  $\text{HNO}_3$  converts it into trichloroacetic acid. When pure it gives no precipitate with silver nitrate solution, and is not browned by contact with concentrated  $\text{H}_2\text{SO}_4$ . Under the influence of sunlight it is violently decomposed by potassium chlorate. Chlorin, phosgene gas, carbon dioxide, and chloroform are given off, and after a time, crystals of potassium trichloroacetate separate from the cooled mixture.

Chloral also combines with alcohol, with elevation of temperature, to form a solid, crystalline body—chloral alcoholate:  $\text{C}(\text{Cl}_3)-\text{CH} \begin{array}{l} \nearrow \text{OH} \\ \searrow \text{O}-(\text{C}_2\text{H}_5)_n \end{array}$ .

**Action of Chloral Hydrate upon the Economy.**—Although it was the ready decomposition of chloral into a formiate and chloroform which first suggested its use as a hypnotic to Liebreich, and although this decomposition was at one time believed to occur in the body under the influence of the alkaline reaction of the blood, more recent investigations have shown that the formation of chloroform from chloral in the blood is, to say the least, highly improbable, and the chloral has, in common with

many other chlorinated derivatives of this series, the property of acting directly upon the nerve-centres.

Neither the urine nor the expired air contains chloroform when chloral is taken internally; when taken in large doses, chloral appears in the urine. The fact that the action of chloral is prolonged for a longer period than that of the other chlorinated derivatives of the fatty series is probably due, in a great measure, to its less volatility and less rapid elimination.

When taken in overdose, chloral acts as a poison, and its use as such is rapidly increasing as acquaintance with its powers becomes more widely disseminated.

No chemical antidote is known. The treatment should be directed to the removal of any chloral remaining in the stomach by the stomach-pump, and to the maintenance or restoration of respiration.

In fatal cases of poisoning by chloral that substance may be detected in the blood, urine, and contents of the stomach by the following method: the liquid is rendered strongly alkaline with potassium hydrate; placed in a flask, which is warmed to 50–60 (122–140° F.), and through which a slow current of air, heated to the same temperature, is made to pass; the air, after bubbling through the liquid, is tested for chloroform by the methods described on p. 234. If affirmative results are obtained in this testing, it remains to determine whether the chloroform detected existed in the fluid tested in its own form, or resulted from the decomposition of chloral; to this end a fresh portion of the suspected liquid is *rendered acid* and tested as before. A negative result is obtained in the second testing when chloral is present.

**Bromal**— $\text{CBr}_3\text{COH}$ —281.—A colorless, oily, pungent liquid; sp. gr. 3.34; boils at 172 (341.6° F.); neutral; soluble in  $\text{H}_2\text{O}$ , alcohol, and ether. It combines with  $\text{H}_2\text{O}$  to form bromal hydrate,  $\text{CBr}_3\text{CH}(\text{OH})_2$ ; large transparent crystals; soluble in  $\text{H}_2\text{O}$ ; decomposed by alkalis into bromoform and a formiate. Produces anaesthesia without sleep; very poisonous.

**Thioaldehydes**.—By the action of  $\text{H}_2\text{S}$  on aldehyde in the presence of  $\text{HCl}$  two products are obtained, having the composition  $(\text{CH}_3\text{CSH})_3$ , known as  $\alpha$  and  $\beta$  **Trithioaldehyde**. The former is in large prismatic crystals, fusible at 101 (213.8° F.), the latter in long needles, fusible at 125°–126° (257°–258.8° F.).

**Propaldehyde**—**Propionic aldehyde**— $\text{CH}_3\text{CH}_2\text{COH}$ —58—obtained by the general reaction from propylic alcohol, is a colorless liquid, resembling acetic aldehyde; boils at 40° (120.2° F.).

**Normal Butaldehyde**—**Butyric aldehyde**— $\text{CH}_3\text{CH}_2\text{CH}_2\text{COH}$ —72—is an oily liquid, boiling at 73 (163.4° F.). Its trichlorinated derivative, **Trichlorobutaldehyde**, or **Butyric chloral**,  $\text{CCl}_3\text{CH}_2\text{COH}$ —is the substance whose hydrate is used as a medicine

under the name croton chloral hydrate. It is a colorless liquid, boiling at 160 (320° F.), obtained by the action of Cl on acetaldehyde.

### ACETALS.

These substances may be considered as derived from the aldehydes by the substitution of two groups OR (R = an alcoholic radical  $C_nH_{2n+1}$ ) for the O of an aldehyde.

**Methylal — Formal**— $CH_2 \begin{smallmatrix} \diagup OCH_3 \\ \diagdown OCH_3 \end{smallmatrix}$ —76—is formed by distilling a mixture of  $MnO_2$ , methyl alcohol,  $H_2SO_4$  and  $H_2O$ . It is a colorless liquid; sp. gr. 0.8551 at 17° (62.6° F.), boiling at 42° (107.6° F.); soluble in  $H_2O$ , alcohol, and oils. It has a burning, aromatic taste and an odor resembling those of chloroform and acetic acid. It has been used as a hypnotic.

**Acetal**— $CH_2 \begin{smallmatrix} \diagup OC_2H_5 \\ \diagdown OC_2H_5 \end{smallmatrix}$ —104—a colorless liquid, boils at 104° (219.2° F.), sp. gr. 0.8314; sparingly soluble in  $H_2O$ , readily in alcohol; obtained by heating a mixture of aldehyde, alcohol and glacial acetic acid, or in the same manner as formal, using ethylic in place of methylic alcohol.

### KETONES OR ACETONES.

#### SERIES $C_nH_{2n}O$ .

These substances all contain the group of atoms  $(CO)''$ , and their constitution may be represented graphically thus:

Dimethyl ketone  
(acetone).

Methyl-ethyl ketone.

the first being a symmetrical ketone and the latter an unsymmetrical. The ketones are isomeric with the aldehydes, from which they are distinguished: 1st, by the action of H, which produces a primary alcohol with an aldehyde, and a secondary alcohol with a ketone:

Propionic aldehyde.

Propyl alcohol.

2d, by the action of O, which unites directly with an aldehyde to produce the corresponding acid, while it causes the disruption of the molecule of the ketone, with formation of two acids :

**Dimethyl ketone—Acetone—Acetylmethylid—Pyroacetic ether** or *spirit*— $\text{CO} \begin{array}{l} \text{CH}_3 \\ \diagup \quad \diagdown \\ \text{CH}_3 \end{array}$ —58—is formed as one of the products of the dry distillation of the acetates ; by the decomposition of the vapor of acetic acid at a red heat ; by the dry distillation of sugar, tartaric acid, etc. ; and in a number of other reactions. It is obtained by distilling dry calcium acetate in an earthenware retort at a dull red heat ; the distillate, collected in a well-cooled receiver, is freed from  $\text{H}_2\text{O}$  by digestion with fused calcium chlorid, and rectified ; those portions being collected which pass over at  $60^\circ$  ( $140^\circ \text{ F.}$ ). It is also formed in large quantity in the preparation of anilin.

It is a limpid, colorless liquid ; sp. gr. 0.7921 at  $18^\circ$  ( $64.4^\circ \text{ F.}$ ) ; boils at  $56^\circ$  ( $132.8^\circ \text{ F.}$ ) ; soluble in  $\text{H}_2\text{O}$ , alcohol, and ether ; has a peculiar, ethereal odor, and a burning taste ; is a good solvent of resins, fats, camphor, gun-cotton ; readily inflammable. It forms crystalline compounds with the alkaline bisulphites. Cl and Br, in the presence of alkalis, convert it into chloroform or bromoform ; Cl alone produces with acetone a number of chlorinated products of substitution. Certain oxidizing agents transform it into a mixture of formic and acetic acids ; others into oxalic acid.

Acetone has been found to exist in the blood and urine in certain pathological conditions, and notably in diabetes : the peculiar odor exhaled by diabetics is produced by this substance.

which has also been considered as being the cause of the respiratory derangements and coma which frequently occur in the last stages of the disease.

That acetone exists in the blood in such cases is certain; it is not certain, however, that its presence produces the condition designated as *acetonæmia*. It can hardly be doubted that the acetone thus existing in the blood is indirectly formed from diabetic sugar, and it is probable also that a complex acid, known as *ethyldiacetic*,  $C_6H_7O_5H$ , is formed as an intermediate product.

See aromatic ketones.

### NITROPARAFFINS.

There exist two distinct isomeric series having the composition  $C_nH_{2n+1}NO_2$ . One contains the true nitrous ethers (see compound ethers), formed by the substitution of the hydrocarbon radical for the hydrogen of nitrous acid, and having the constitution  $O=N-O$ ,  $CH_3 =$  methyl nitrite. The other contains substances in which the hydrocarbon radical is directly attached to the N atom, which may be considered as paraffins in which the group  $(NO_2)$  has taken the place of an atom of hydrogen, and

have the constitution  $\begin{array}{c} O \\ | \\ \text{---} \end{array} N-CH_3 =$  nitromethane.

These bodies are formed by the action of the monoiodic derivatives of the paraffins upon silver nitrite :

These are converted by nascent hydrogen into amidoparaffins or monamins :

These are decomposed by  $H_2SO_4$  or  $HCl$  into hydroxylammonium salts, and acids  $C_nH_{2n}O_2$ , containing all the C :

Nitrous acid converts the primary nitroparaffins into powerful acids, called *nitrolic acids*, having the general formula :  $C_nH_{2n+1}$

$-\text{C} \begin{array}{l} \nearrow \text{NOH} \\ \searrow \text{NO}_2 \end{array}$ . But the same agent converts the secondary nitroparaffins into *pseudonitrols*, having the general formula :

## MONAMINS—AMIDOPARAFFINS.

The **monamins** are substances which may be considered as being derived from one molecule of  $\text{NH}_3$  by the substitution of one, two, or three alcoholic radicals for one, two, or three H atoms. They are designated as **primary**, **secondary**, and **tertiary**, according as they contain one, two, or three alcoholic radicals :

They are also known as **compound ammonias**, and resemble ammonia in their chemical properties ; uniting with acids, without elimination of  $\text{H}_2\text{O}$ , to form salts resembling those of ammonium. They also combine with  $\text{H}_2\text{O}$  to form **quaternary ammonium hydrates**, similar in constitution to ammonium hydrate. The alkalinity and solubility in  $\text{H}_2\text{O}$  of the primary monamins are greater than those of the secondary, and those of the secondary greater than those of the tertiary. Their chlorids form sparingly soluble compounds with platinic chlorid.

The **primary monamins** are formed by the action of potassium hydrate upon the corresponding cyanic ether :

or by heating together an alcoholic solution of ammonia and an ether :

or by the action of nascent H upon the cyanids of the alcoholic radicals :

The **secondary monamins** are formed by the action of the iodids or bromids of the alcoholic radicals upon the primary monamins :

The **tertiary monamins** are produced by the distillation of the

hydrates or iodids of the quaternary ammoniums, or by the action of the iodids of the alcoholic radicals upon the secondary monamins.

It is obvious from the above-described properties of these substances that they are true alkaloids, among which also belong the diamins and triamins.

**Methylamin**—*Methylia*— $\begin{matrix} \text{CH}_3 \\ \text{H}_2 \end{matrix} \text{N}$ —31—is a colorless gas; has a fishy, ammoniacal odor; inflammable; is the most soluble gas known, one volume of  $\text{H}_2\text{O}$  dissolving 1,154 volumes of methylia at  $12^\circ.5$  ( $54^\circ.5$  F.).

The aqueous solution possesses the odor of the gas, and is highly caustic and alkaline. It neutralizes the acids with formation of methylammonium salts (*e.g.*,  $\text{CH}_3\text{H}_3\text{NNO}_3$  = methylammonium nitrate), which are for the most part crystallizable and very soluble in  $\text{H}_2\text{O}$ . Its chloraurate crystallizes in beautiful golden-yellow needles, soluble in water, alcohol, and ether. Its chloroplatinate crystallizes in golden-yellow scales, soluble in water, insoluble in alcohol.

See trimethylamin, below.

**Dimethylamin**—*Dimethylia*— $\begin{pmatrix} \text{CH}_3 \\ \text{H} \end{pmatrix}_2 \text{N}$ —45—is a liquid below  $8$  ( $46.4$  F.); has an ammoniacal odor, and is quite soluble in  $\text{H}_2\text{O}$ . It constitutes about 50 per cent. of the commercial trimethylamin, which also contains 5 to 10 per cent. of trimethylamin, the remainder being a mixture of monomethylamin, isobutylamin, and propylamin. Its chloroplatinate forms long needles.

See trimethylamin, below.

**Trimethylamin**—*Trimethylia*— $(\text{CH}_3)_3\text{N}$ —59—is formed by the action of methyl iodid upon  $\text{NH}_3$ , and as a product of decomposition of many organic substances, it being one of the products of the action of potash on many vegetable substances, alkaloids, etc. It also occurs naturally in cod-liver oil, ergot, chenopodium, yeast, guano, human urine, the blood of the calf, and many flowers.

It is an oily liquid, having a disagreeable odor of fish; boils at  $8$  ( $48.2$  F.); alkaline; soluble in  $\text{H}_2\text{O}$ , alcohol, and ether; inflammable. It combines with acids to form salts of trimethylammonium, which are crystallizable.

Trimethylamin has long been known to exist in the pickle in which herrings have been preserved. More recently it has been found to be an important product of putrefactive changes in fish, starch-paste, brain-tissue, muscular tissue, and other albuminoid substances, being accompanied by lesser quantities of monomethylamin, dimethylamin, ethylamin, and diethylamin, as well as by other peculiar alkaloidal bodies. It has also been observed accompanying more active alkaloids in blood-serum, etc., which

have served for the culture of various bacilli. See cholin and neurin, below, and ptomains.

Its chloroplatinate crystallizes in octahedra, insoluble in alcohol.

The commercial trimethylamin, obtained by the dry distillation of distillery-waste, contains but  $\frac{1}{10}$  per cent. of the substance whose name it bears. (See dimethylamin, above.) It has frequently been mistaken by writers upon materia medica for its isomere *propylamin*.  $(\text{C}_3\text{H}_7) \begin{smallmatrix} \text{N} \\ \text{H}_2 \end{smallmatrix}$ , which differs from it in odor, and in boiling at  $50^\circ$  ( $122^\circ$  F.). Its chlorid, under the names chlorid of propylamia, of secalia, of secalin, has been used in the treatment of gout and of rheumatism.

**Tetramethyl ammonium hydrate**— $(\text{CH}_3)_4\text{NOH}$ —91.—This substance, whose constitution is similar to that of ammonium hydrate, is obtained by decomposing the corresponding iodid  $(\text{CH}_3)_4\text{NI}$ , formed by the action of methyl iodid upon trimethylamin. It is a crystalline solid; deliquescent; very soluble in  $\text{H}_2\text{O}$ ; caustic; not volatile without decomposition. It attracts carbon dioxid from the air, and combines with acids to form crystallizable salts.

The iodid is said to exert an action upon the economy similar to that of curare.

**Cholin**—*Trimethyloxethylammonium hydrate*—

$(\text{CH}_3)_3 \begin{smallmatrix} \text{N}, \text{OH} \\ (\text{CH}_2, \text{CH}_2 - \text{OH}) \end{smallmatrix} = \text{C}_5\text{H}_{15}\text{NO}_2$ —121—is a quaternary monammonium hydrate, containing three methyl groups and one ethylene hydroxid (oxethyl) group. It does not occur in the normal body in the free state, but is widely disseminated as a component part of an exceedingly important class of substances, the lecithins. It is also obtained from bile and from the yolk of eggs. It is one of the earliest products of cadaveric putrefaction, resulting, in all probability, from decomposition of the lecithins.

Cholin has been obtained synthetically by the action of a concentrated solution of trimethylamin upon ethylene oxid, or upon ethylene chlorhydrin. When heated, it splits up into glycol and trimethylamin.

It appears as a thick syrup, soluble in  $\text{H}_2\text{O}$  and in alcohol, and strongly alkaline in reaction. Even in dilute aqueous solution it prevents the coagulation of albumin and redissolves coagulated albumin and fibrin. It is a strong base; attracts carbon dioxid from the air; forms with  $\text{HCl}$  a salt, soluble in alcohol, which crystallizes in plates and needles, very much resembling in appearance those of cholesterin. Its chloroplatinate is purified with difficulty; its chloraurate readily. Solutions of its chlorid differ in their behavior with alkaloidal reagents from those of neurin

in forming no precipitate with tannic acid, and in forming a voluminous white precipitate with phosphomolybdic acid, which becomes crystalline on standing.

Administered hypodermically to animals it causes muscarin-like intoxication, although much less intense in its action than either that alkaloid or neurin.

**Amanitin**—*Trimethyloxethylideneammonium hydrate*—

$\left. \begin{array}{l} (\text{CH}_3)_3 \\ (\text{CH}_3-\text{CHOH}) \end{array} \right\} \text{N.OH} = \text{C}_5\text{H}_{15}\text{NO}_2 - 121$ —is an isomere of cholin existing along with muscarin (see below) in *Agaricus muscarius*. By oxidation with  $\text{HNO}_3$  it yields muscarin.

**Muscarin**— $\left. \begin{array}{l} (\text{CH}_3)_3 \\ (\text{C}_2\text{H}_5\text{O}_2) \end{array} \right\} \text{N.OH} = \text{C}_5\text{H}_{15}\text{NO}$ .—is a substituted tetramethylammonium hydrate closely related to cholin and amanitin, from the former of which it may be obtained by oxidation.

It occurs in nature in *Agaricus muscarius*, and is produced during putrefactive decomposition of albuminoid substances.

The free alkaloid occurs in very deliquescent, irregular crystals, or, if not perfectly dry, a colorless, odorless, and tasteless, but strongly alkaline syrup; readily soluble in all proportions in water and in alcohol; very sparingly soluble in chloroform; insoluble in ether. It is a more powerful base than ammonium hydrate, forming an alkaline carbonate and neutral salts with other acids. When decomposed it yields trimethylamin. Its chloroplatinate crystallizes in octahedra. Its chlorid forms colorless, brilliant, deliquescent needles.

When administered to animals, muscarin causes increased secretion of saliva and tears; vomiting; evacuation of faeces, at first solid, later liquid; contraction of the pupils, almost to the extent of closure; diminution of the rapidity of the pulse; interference with respiration and locomotion; gradual sinking of the heart's action and respiration; and death. Atropin prevents the action of muscarin, and diminishes its intensity when already established.

**Neurin**—*Trimethylvinylammonium hydrate*— $\left. \begin{array}{l} (\text{CH}_3)_3 \\ (\text{C}_2\text{H}_5) \end{array} \right\} \text{NOH} = \text{C}_7\text{H}_{13}\text{NO}$ —is a substance nearly related to cholin, and long confounded with it, supposed by Liebreich to exist in the brain. The same body is one of the alkaloids produced by the putrefaction of muscular tissues, and is endowed with poisonous qualities, resembling, but less intense than, those of muscarin.

Another cadaveric alkaloid, related to neurin and produced under similar conditions, is a diamine: **neuridin**,  $\text{C}_6\text{H}_{14}\text{N}_2$ .

## MONAMIDS.

These bodies differ from the amines in containing *oxygenated*, or *acid* radicals, in place of alcoholic radicals. Like the amines, they are divisible into **primary**, **secondary**, and **tertiary**. They are the nitrids of the acid radicals, as the amines are the nitrids of the alcoholic radicals.

The monamids may also be regarded as the acids in which the OH of the group COOH has been replaced by (NH<sub>2</sub>) :

The **primary monamids**, containing radicals of the acids of the acetic series, are formed : (1.) By the action of heat upon an ammoniacal salt :

(2.) By the action of a compound ether upon ammonia :

(3.) By the action of the chlorid of an acid radical upon dry NH<sub>3</sub> :

The **secondary monamids** of the same class are obtained : (1.) By the action of the chlorids of acid radicals upon the primary amids :

(2.) By the action of HCl upon the primary monamids at high temperatures :

The **tertiary monamids** of this series of radicals have been but

imperfectly studied; some of them have been obtained by the action of the chlorids of acid radicals upon metallic derivatives of the secondary amids.

The **primary monamids** containing radicals of the fatty acids are solid, crystallizable, neutral in reaction, volatile without decomposition, mostly soluble in alcohol and ether, and mostly capable of uniting with acids to form compounds similar in constitution to the ammoniacal salts. They are capable of uniting with  $H_2O$  to form the ammoniacal salt of the corresponding acid, and with the alkaline hydrates to form the metallic salt of the corresponding acid and ammonia. The **secondary monamids**, containing two radicals of the fatty series, are acid in reaction, and their remaining atom of extra-radical H may be replaced by an electro-positive atom.

**Formamid**— $CHO.H_2N$ —45—is a colorless liquid, soluble in  $H_2O$  and in alcohol, boils at  $192-195$  ( $377.6-385$  F.), suffering partial decomposition, obtained by heating ethyl formiate with an alcoholic solution of ammonia, or by the dry distillation of ammonium formiate. It is decomposed by dehydrating agents, with formation of hydrocyanic acid. **Mercury formamid** is obtained in solution by gently heating freshly precipitated mercuric oxid with  $H_2O$  and formamid.

Under the name **chloralamid** a compound, formed by the union of chloral and formamid, and having the constitution,

$CCl_3CH \begin{matrix} \text{OH} \\ \diagup \\ \text{NHCHO} \end{matrix}$ , has been recently used as a hypnotic. It forms colorless, odorless, faintly bitter crystals, fusible at  $115^\circ$  ( $239$  F.), sparingly soluble in water. It is decomposed by alkalis, chloroform and ammonia being among the products of the decomposition. It is not affected by acids.

**Chloralimid**— $CCl_3.C \begin{matrix} \text{N-H} \\ \diagup \\ \text{H} \end{matrix}$ —is another related derivative, formed by the action of ammonium acetate upon chloral hydrate, or by the action of heat upon chloral ammonia. It is a crystalline solid, sparingly soluble in water, readily soluble in ether and in alcohol. When heated to  $180$  ( $356$  F.) it is decomposed into chloroform and formamid.

**Acetamid**— $(C_2H_5O) \begin{matrix} \text{N-H} \\ \diagup \\ \text{H} \end{matrix}$ —59—is obtained by heating, under pressure, a mixture of ethyl acetate and aqua ammonia, and purifying by distillation. It is a solid, crystalline substance, very soluble in  $H_2O$ , alcohol, and ether; fuses at  $78$  ( $172.4$  F.); boils at  $221$  ( $429.8$  F.); has a sweetish, cooling taste, and an odor of mice. Boiling potassium hydrate solution decomposes it into potassium acetate and ammonia. Phosphoric anhydrid deprives it of  $H_2O$ , and forms with it **acetonitril** or **methyl cyanid**.

## AMIDO-ACIDS OF THE FATTY SERIES.

These compounds, also known as **glycocols**, are of mixed function, acid and basic, obtained by the substitution of the univalent group ( $\text{NH}_2$ ) for an atom of radical H of an acid :

Some of them, and many of their derivatives, exist in animal bodies. Corresponding to them are many isomeres belonging to other series.

**Amido-acetic acid—Glycocol—Sugar of gelatin—Glycolamic acid—(Glycin—**

$$\begin{array}{c} \text{CH}_2\text{NH}_2 \\ | \\ \text{COOH} \end{array}$$

**—75—** was first obtained by the action of

$\text{H}_2\text{SO}_4$  upon gelatin. It is best prepared by acting upon glue with caustic potassa,  $\text{NH}_3$  being liberated ;  $\text{H}_2\text{SO}_4$  is then added, and the crystals of potassium sulphate separated : the liquid is evaporated, the residue dissolved in alcohol, from which solution the glycocol is allowed to crystallize.

It may also be obtained synthetically by a method which indicates its constitution—by the action of ammonia upon chloracetic acid :

It may be obtained from ox-bile, in which it exists as the salt of a conjugate acid ; from uric acid by the action of hydriodic acid ; and by the union of formic aldehyde, hydrocyanic acid and water. It is isomeric with **glycolamid**— $\begin{array}{c} \text{CH}_2\text{OH} \cdot \text{C}(\text{O}) \\ | \\ \text{H}_2 \end{array} \text{N}$ .

It has been found to exist free in animal nature only in the muscle of the scallop, and, when taken internally, its constituents are eliminated as urea. In combination it exists in the gelatinoids, and with cholic acid as sodium glycocholate (*q. v.*) in the bile. It is one of the products of decomposition of glycocholic acid, hyoglycocholic acid, and hippuric acid by dilute acids and by alkalies, and of the decomposition of tissues containing gelatinoids.

It appears as large, colorless, transparent crystals : has a sweet taste ; melts at  $170^\circ$  ( $338^\circ \text{ F.}$ ) ; decomposes at higher temperatures ; sparingly soluble in cold  $\text{H}_2\text{O}$  ; much more soluble in warm  $\text{H}_2\text{O}$  ; insoluble in absolute alcohol and in ether ; acid in reaction.

It combines with acids to form crystalline compounds, which are decomposed at the temperature of boiling water; hot  $\text{H}_2\text{SO}_4$  carbonizes it;  $\text{HNO}_3$  converts it into glycolic acid (*q. v.*); with  $\text{HCl}$  it forms a chlorid; heated under pressure with benzoic acid it forms hippuric acid. Its acid function is more marked; it expels carbonic and acetic acids from calcium carbonate and plumbic acetate. The presence of a small quantity of glycolol prevents the precipitation of cupric hydrate from cupric sulphate solution by potassium hydrate; the solution becomes dark blue, does not yield cuprous hydrate on boiling, and precipitates crystalline needles of copper glycolamate on the addition of alcohol to the cold solution. With ferric chlorid it gives an intense red solution, whose color is discharged by acids, and reappears on neutralization. With phenol and sodium hypochlorite it gives a blue color, as does ammonia. By oxidation with potassium permanganate in alkaline solution it yields carbon dioxide, oxalic, carbonic, and oxamic acids, and water. It also forms crystalline compounds with many salts and ethers. Methyl amido-acetate is isomeric with sarcosin.

alanin and with lactamid (*q. v.*), does not exist as such in animal nature, but has been obtained from creatin (*q. v.*) by the action of barium hydrate :

urea being formed at the same time, and decomposed by the further action of the barium hydrate into  $\text{NH}_3$  and barium carbonate.

Its constitution is indicated by its synthetic formation from chloracetic acid and methylamin :

It crystallizes in colorless, transparent prisms; very soluble in water; sparingly soluble in alcohol and ether. Its aqueous solution is not acid, and has a sweetish taste; it unites with acids to

form crystalline salts, but does not form metallic salts. It is capable of combining with cyanamid to form creatin.

**Betain**—*Trimethylglycocol*—*Oxyneurin*—*Oxycholin*—

$$\begin{array}{c} \text{CH}_3\text{—CO} \\ | \\ (\text{CH}_3)_3\text{N} \text{—} \text{O} \end{array} = \text{C}_5\text{H}_{11}\text{NO}_2\text{—}117\text{—}$$
 was first obtained from the juice of the sugar-beet; afterward it was obtained by oxidation of cholin; and is also produced synthetically, either by acting upon trimethylamin with monochloroacetic acid, as glycocol is obtained by the action of the same acid upon ordinary ammonia; or by acting upon glycocol itself with methyl iodid.

Betain crystallizes in large, brilliant crystals, containing one molecule of water of crystallization. At the ordinary temperature they are deliquescent, but effloresce at 100° (212° F.). It is very soluble in water and in alcohol. It is decomposed by heat, with evolution of trimethylamin. It forms crystalline salts. Its chloraurate is crystalline, and very sparingly soluble in cold water.

The method of its synthesis and the composition of its chlorid indicate it to be related to tetramethylammonium hydrate, but when its chlorid is decomposed by silver oxid, it is not with substitution of OH for Cl, but with separation of Cl + H<sub>2</sub>O.

Betain is the type of a number of similar compounds derivable from the amido-acids by substitution of various hydrocarbon radicals.

**Amidopropionic Acid—Alanin**—
$$\begin{array}{c} \text{CH}_3\text{—CH}_2\text{(NH}_2\text{)} \\ | \\ \text{COOH} \end{array}$$
 —89.—Isomeric

with sarcosin and with lactamid; does not exist, as far as is known at present, in nature. It is obtained by the action of alcoholic ammonia upon bromopropionic acid:

It may also be prepared by starting from lactic acid, from which it differs by containing NH<sub>2</sub> in place of OH.

It crystallizes in large, oblique, rhombic prisms; very soluble in H<sub>2</sub>O; sparingly soluble in alcohol; insoluble in ether. Its aqueous solution is neutral and sweet. Nitrous acid converts it into lactic acid, N, and H<sub>2</sub>O. It dissolves in acids without neutralizing them, but yet, in certain cases, with the formation of crystalline compounds. Its Ba, Pb, Cu, and Ag salts are soluble and crystalline.

**Amidobutyric Acid—Butalanin**— $\text{C}_4\text{H}_9\text{NO}_2$ —and **Amidovalerianic acid**— $\text{C}_5\text{H}_{11}\text{NO}_2$ —are only of theoretic interest at present.

The latter has been found in the tissue of the pancreas and among the products of the action of pancreatic juice upon albumin. They are among the products of the decomposition of albumin by caustic baryta.

—131—has been obtained from the normal spleen, pancreas, salivary, lymphatic, thymus, and thyroid glands, lungs, and liver. Pathologically, its quantity in the liver is much increased in diseases of that organ, and in typhus and variola; in the bile in typhus; in the blood in leucocythæmia, and in yellow atrophy of the liver; in the urine in yellow atrophy of the liver, in typhus, and in variola; in choleraic discharges from the intestine; in pus; in the fluids of dropsy; and of atheromatous cysts. In these situations it is usually accompanied by tyrosin (*q. v.*).

It is formed along with tyrosin by the decomposition of nitrogenized animal and vegetable substances, by heating with strong alkalies or dilute acids; and is one of the products of putrefaction. It is best obtained by the action of hot dilute  $\text{H}_2\text{SO}_4$  on bone shavings. It has also been formed synthetically by the action of  $\text{NH}_3$  upon bromocaproic acid, in the same way that alanin is formed from bromopropionic acid (see above).

Leucin crystallizes from alcohol in soft, pearly plates, lighter than  $\text{H}_2\text{O}$ , and somewhat resembling cholesterin; sometimes in round masses composed of closely grouped needles radiating from a centre. It is sparingly soluble in cold  $\text{H}_2\text{O}$ ; readily in warm  $\text{H}_2\text{O}$ ; almost insoluble in cold alcohol and ether; soluble in boiling alcohol; it is odorless and tasteless, and its solutions are neutral. It sublimes at  $170^\circ$  ( $338^\circ \text{F.}$ ) without decomposition; if suddenly heated above  $180^\circ$  ( $356^\circ \text{F.}$ ), it is decomposed into amylamin and carbon dioxid.

When heated to  $140^\circ$  ( $284^\circ \text{F.}$ ), with hydriodic acid under pressure, it is decomposed into caproic acid and ammonia. Nitrous acid converts it into leucic acid,  $\text{C}_6\text{H}_{12}\text{O}_3$ ,  $\text{H}_2\text{O}$  and  $\text{N}$ . It unites with acids to form soluble, crystalline salts. It also dissolves readily in solutions of alkaline hydrates, forming crystalline compounds with the metallic elements.

The formation of leucin in the body is one of the steps of the transformation of at least some part of the albuminoids into urea. When leucin and tyrosin appear in the urine, that fluid is poor in urea and usually contains biliary coloring matters; the substitution of leucin for urea may be so extensive that the urine contains no urea, and contains leucin in such quantity that it crystallizes out spontaneously.

The presence of leucin and tyrosin in the urine may be detected

as follows: the freshly collected urine is treated with basic lead acetate, filtered, the filtrate treated with  $\text{H}_2\text{S}$ , filtered from the precipitated lead sulphid, and the filtrate evaporated over the water-bath; leucin and tyrosin crystallize: they may be separated by extraction of the residue with hot alcohol, which dissolves the leucin and leaves the tyrosin. The leucin left by evaporation of the alcoholic solution may be recognized by its crystalline form and by the following characters: (1) a small portion is moistened on platinum foil with  $\text{HNO}_3$ , which is then cautiously evaporated; a colorless residue remains, which, when warmed with caustic soda solution, turns yellow or brown, and by further concentration is converted into oily drops, which do not adhere to the platinum (Scherer's test); (2) a portion of the residue is heated in a dry test-tube; it melts into oily drops, and the odor of amylamin (odor of ammonia combined with that of fusel oil) is observed; (3) if a boiling mixture of leucin and solution of neutral lead acetate be carefully neutralized with ammonia, brilliant crystals of a compound of leucin and lead oxid separate; (4) leucin carefully heated in a glass tube, open at both ends, to  $170^\circ$  ( $338^\circ \text{F.}$ ), sublimes without fusing, and condenses in flocculent shreds. If heated beyond  $180^\circ$  ( $356^\circ \text{F.}$ ), the decomposition mentioned in (2) occurs.

**Tyrosin**— $\text{C}_9\text{H}_{11}\text{NO}_3$ —145—is probably an amido-acid belonging among the aromatic compounds. As its constitution is not determined, and as it always accompanies leucin in nature, it is best considered here.

The methods of its formation are given under leucin. It crystallizes from its watery and ammoniacal solutions in silky needles, arranged in stellate bundles; very sparingly soluble in cold  $\text{H}_2\text{O}$ ; almost insoluble in alcohol; more soluble in hot  $\text{H}_2\text{O}$ . When heated, it turns brown and yields an oily matter having the odor of phenol; when heated in small quantities to  $270^\circ$  ( $518^\circ \text{F.}$ ), it is decomposed into carbon dioxid and a white solid, having the composition  $\text{C}_8\text{H}_{11}\text{NO}$ , which sublimes. It combines with both acids and bases.

When taken into the stomach it is not altered in the economy, but is eliminated in the urine and fæces.

When moistened with  $\text{HNO}_3$  and carefully evaporated, a deep yellow residue remains, which turns darker with  $\text{NaHO}$ . With concentrated  $\text{H}_2\text{SO}_4$  and slightly warmed, it dissolves with a transient red color—the solution, filtered and neutralized with  $\text{CaCO}_3$ , gives a violet color with  $\text{Fe}_2\text{Cl}_6$  solution.

**Biliary Acids.**—The bile of most animals contains the sodium salts of two amido-acids of complex constitution. These acids may be decomposed into a non-nitrogenized acid (cholic acid), and either an amido-acid (glycocol), or an amido-sulphurous acid (taurin). The following biliary acids have been described:

**Glycocholic acid**— $\text{C}_{26}\text{H}_{43}\text{NO}_6$ —465—exists as its sodium salt in the bile of the herbivora, and in much smaller proportion in that of the carnivora; it exists in small quantity in human blood and urine in icterus.

It is best obtained from ox-bile; this is evaporated to one-fourth of its original volume, the residue is ground up with animal charcoal, and dried at 100° (212° F.); the dry mass, while still hot, is broken up and introduced into a flask, in which it is digested with absolute alcohol, with repeated agitation, for some days; the colorless, filtered alcoholic solution is partially evaporated, but not to the extent of becoming syrupy, then mixed with an excess of anhydrous ether, which, if the reagents were free from  $\text{H}_2\text{O}$ , causes the immediate separation of a crystalline precipitate of the mixed biliary salts. If the alcohol or ether used contain  $\text{H}_2\text{O}$ , the precipitate is at first resinous and only becomes crystalline after standing, or does not become crystalline if the proportion of  $\text{H}_2\text{O}$  be too great. The crystalline deposit is collected upon a filter, washed with ether and dissolved in a small quantity of  $\text{H}_2\text{O}$ ; to the aqueous solution a small quantity of ether is added, and then enough dilute  $\text{H}_2\text{SO}_4$  to render the mixture permanently cloudy; the glycocholic acid gradually crystallizes out, and may be further purified by solution in alcohol, and precipitation with a great excess of ether.

Glycocholic acid forms brilliant, colorless, transparent needles, which are sparingly soluble in cold  $\text{H}_2\text{O}$ , readily soluble in warm  $\text{H}_2\text{O}$  and in alcohol, almost insoluble in ether. The watery solution is acid in reaction, and tastes at first sweet, afterward intensely bitter. Its alcoholic solution exerts a right-handed polarization  $[\alpha]_D = +29^\circ$ .

When heated with potash, baryta, or dilute  $\text{H}_2\text{SO}_4$ , or  $\text{HCl}$ , it is decomposed into cholic acid and glyccol:

Glycocholic acid dissolves unchanged in cold concentrated  $\text{H}_2\text{SO}_4$ , and is precipitated on dilution of the solution with  $\text{H}_2\text{O}$ . If the mixture be warmed the bile acid is decomposed, and there separate oily drops of cholonic acid,  $\text{C}_{26}\text{H}_{41}\text{NO}_5$ , differing from glycocholic acid by  $-\text{H}_2\text{O}$ . When allowed to remain long in contact with concentrated  $\text{H}_2\text{SO}_4$ , glycocholic acid is converted into a colorless, resinous mass, which slowly forms a saffron-yellow solution with the mineral acid, which turns flame-red when warmed, and which, on dilution, deposits a flocculent material which is colorless, greenish, or brownish, according to the temperature at which it is formed. Glycocholic acid, altered by contact with concentrated  $\text{H}_2\text{SO}_4$ , absorbs O when exposed to the air, and turns red, then blue, and finally brown after a few days.

Sodium Glycocholate,  $\text{C}_{26}\text{H}_{42}\text{NO}_6\text{Na}$ , exists in the bile; it crystallizes in stellate needles, very soluble in  $\text{H}_2\text{O}$ , less so in absolute alcohol, and insoluble in ether; its alcoholic solution exerts right-handed polarization  $[\alpha]_D = +25^\circ.7$ .

Lead Glycocholate,  $(\text{C}_{26}\text{H}_{42}\text{NO}_6)_2\text{Pb}$  (?), is formed as a white, flocculent precipitate, when solution of lead subacetate is added

to a solution of a glycocholate or of glycocholic acid ; with the *neutral* acetate the precipitation does not occur in the presence of an excess of acetic acid. It is soluble in alcohol, and in an excess of lead acetate solution.

The glycocholates of the alkaline earths are soluble in  $H_2O$ . Glycocholic acid and the glycocholates react with Pettenkofer's test (see below).

Glycocholic acid forms compounds with the alkaloids, some of which are crystalline, others amorphous ; they are for the most part very sparingly soluble in  $H_2O$ , but readily soluble in solutions of the biliary salts and in bile.

**Taurocholic acid**— $C_{26}H_{45}NO_7S$ —515—exists as its sodium salt in the bile of man and of the carnivora, and in much less abundance in that of the herbivora. In the bile of the dog it seems to be unaccompanied by any other biliary acid. It may be obtained from dog's bile by a modification of the method described under glycocholic acid ; the watery solution is not treated with  $H_2SO_4$ , as in the preparation of that acid, but with solution of basic lead acetate and ammonia. The precipitate so formed is extracted with boiling alcohol, the solution filtered hot and treated with  $H_2S$  ; the clear liquid, filtered from the precipitated lead sulphid, is evaporated to a small bulk and treated with a large excess of ether ; the acid is precipitated in the resinous form, but, after standing for a varying period, assumes the crystalline form.

It forms silky, crystalline needles, which, when exposed to the air, deliquesce rapidly, and which, even under absolute ether, are gradually converted into a transparent, amorphous, resinous mass. It is soluble in  $H_2O$  and alcohol ; insoluble in ether ; its aqueous solution is very bitter ; in alcoholic solution it deviates the plane of polarization to the right,  $[a]_D = +24.5$  ; its solutions are acid in reaction.

Taurocholic acid is decomposed by heating with barium hydrate, with dilute acids, and even by evaporation of its solution, into cholic acid and **taurin** :

The same decomposition occurs in the presence of putrefying material, and in the intestine. Taurocholic acid has not been found to accompany glycocholic in the urine of icteric patients.

The taurocholates are neutral in reaction ; those of the alkaline metals are soluble in alcohol and in water ; and by long contact with ether they assume the crystalline form. They may be separated from the glycocholates in watery solution, either : (1) by dilute  $H_2SO_4$  in the presence of a small quantity of ether, which precipitates glycocholic acid alone ; or (2) by adding *neu-*

*tral* lead acetate to the solution of the mixed salts (which must be neutral in reaction) lead glycocholate is precipitated and separated by filtration. To the mother liquor basic lead acetate and ammonia are added, when lead taurocholate is precipitated. The acids are obtained from the hot alcoholic solutions of the Pb salts by decomposition with  $H_2S$ , filtration, concentration, and precipitation by ether.

Solutions of the taurocholates, like those of the glycocholates, have the power of dissolving cholesterin and of emulsifying the fats. They also form with the salts of the alkaloids compounds which are insoluble in  $H_2O$ , but soluble in an excess of the biliary salt. The taurocholate of morphin is crystallizable. They react with Pettenkofer's test.

Hyoglycocholic acid,  $C_{27}H_{43}NO_5$ , and Hyotaurocholic acid,  $C_{27}H_{43}NO_5S$  (?), are conjugate acids of hyocholic acid,  $C_{25}H_{41}O_4$ , and glycochol and taurin, which exist in the bile of the pig. Chenotaurocholic acid, a conjugate acid of taurin and chenocholic acid,  $C_{27}H_{43}O_4$ , is obtained from the bile of the goose.

Cholic acid— $C_{24}H_{41}O_5$ —408—is a product of decomposition of glyco- and taurocholic acids, obtained as indicated above. It also occurs, as the result of a similar decomposition, in the intestines and faeces of both herbivora and carnivora. It forms large, clear, deliquescent crystals: sparingly soluble in  $H_2O$ , readily soluble in alcohol and ether: intensely bitter in taste, with a sweetish after-taste. In alcoholic solution it is dextrogyrous  $[a]_D = +35$ . The alkaline cholates are crystallizable and readily soluble in  $H_2O$ , the others difficultly soluble. Cholic acid and the cholates respond to Pettenkofer's test.

By boiling with acids or by continued heating to  $200$  ( $392^\circ F.$ ), cholic acid loses the elements of  $H_2O$ , and is transformed into dyslysin,  $C_{24}H_{36}O_3$ , a neutral, resinous material, insoluble in  $H_2O$  and alcohol, sparingly soluble in ether.

**The Pettenkofer Reaction.**—All of the biliary acids, and the cholic acid and dyslysin obtained by their decomposition, have the property of forming a yellow solution with concentrated  $H_2SO_4$ , the color of which rapidly increases in intensity, and which exhibits a green fluorescence. Their watery solutions also, when treated with a small quantity of cane-sugar and with concentrated  $H_2SO_4$ , so added that the mixture acquires a temperature of  $70$  ( $158^\circ F.$ ) but does not become heated much beyond that point, develop a beautiful cherry-red color, which gradually changes to dark reddish-purple. Although this reaction is observed in the presence of very small quantities of the biliary acids, it loses its value, unless applied as directed below, from the fact that many other substances give the same reaction, either with  $H_2SO_4$  alone, or in the presence of cane-sugar. Among

these substances are many which exist naturally in animal fluids, or which may be introduced with the food or as medicines : such are cholesterin, the albuminoids, lecithin, oleic acid, cerebrin, phenol, turpentine, tannic acid, salicylic acid, morphin, codein, many oils and fats, cod-liver oil, etc.

The following method of applying Pettenkofer's test to the urine and other fluids removes, we believe, every source of error. The urine, etc., is first evaporated to dryness at the temperature of the water-bath, a small quantity of coarse animal charcoal having been added ; the residue is extracted with absolute alcohol, the alcoholic liquid filtered, partially evaporated, and treated with ten times its bulk of absolute ether ; after standing an hour or two, any precipitate which may have formed is collected upon a small filter, washed with ether, and dissolved in a small quantity of  $H_2O$  ; this aqueous solution is placed in a test-tube, a drop or two of a strong aqueous solution of cane-sugar (sugar, 1 ; water, 4), and then pure concentrated  $H_2SO_4$  are added ; the addition of the acid being so regulated, and the test-tube dipped from time to time in cold water, that the temperature shall be from  $60^{\circ}$ – $75^{\circ}$  ( $140^{\circ}$ – $167^{\circ}$  F.). In the presence of biliary acids the mixture usually becomes turbid at first, and then turns cherry-red and finally purple, the intensity of the color varying with the amount of biliary acid present.

**Physiological Chemistry of the Biliary Acids.**—These substances are formed in the liver, and they are not reabsorbed from the intestine unchanged. Solutions of the biliary salts, injected into the circulation in small quantity, cause a diminution in the frequency of the pulse and of the respiratory movements, a lowering of the temperature and arterial tension, and disintegration of the blood-corpuscles. In large doses (2–4 grams [30–60 grains] for a dog) they produce the same effects to a more marked degree ; epileptiform convulsions, black and bloody urine, and death more or less rapidly. These effects do not follow the injection of the products of decomposition of the biliary acids, except cholic acid, and in that case the symptoms are much less marked. Nor are the biliary acids discharged unaltered with the fæces ; they are decomposed in the intestine. The extract, suitably purified, of the contents of the upper part of the small intestine, gives a well-marked reaction with Pettenkofer's test ; while similar extracts of the contents of the lower part of the large intestine, or of the fæces, fail to give the reaction, and consequently are free from glyco- or taurocholic, cholic acid, or dyslysin ; the fæces, moreover, do not contain either taurin or glyecocol. During the processes which take place in the intestine, the bile-acids are decomposed into cholic acid and taurin or glyecocol, which are subsequently reabsorbed, either as such, or after having been subjected to further decomposition ; and as a consequence of their decomposition they probably have some influence upon intestinal digestion.

The biliary salts are precipitated from their aqueous solution, or from bile, by fresh gastric juice from the same animal; but they are not so precipitated if the gastric juice contain peptone. The proportion of biliary salts in human bile seems to vary considerably, as shown by the following analyses:

I. Frerichs: Bile from man, æt. 18, killed by a fall. II. Frerichs: Male, æt. 22, died of a wound. III. Gorup-Besanez: Male, æt. 49, decapitated. IV. Gorup-Besanez: Female, æt. 29, decapitated. V. Jacobsen: Male, biliary fistula. VI., VII. Trifanowski: Males. VIII. Socolof: Mean of six analyses of human bile. IX. Hoppe-Seyler: Mean of five analyses of bile from subjects with healthy livers.

Pathologically, the biliary acids may be detected in the blood and urine in icterus and acute atrophy of the liver; although by no means as frequently as the biliary coloring matters.

Creatin— $C_4H_7N_3O_2 + Aq$ —131+18—is another complex amido-acid, which occurs as a normal constituent of the juices of muscular tissue, voluntary and involuntary, of brain, blood, and amniotic fluid.

It is best obtained from the flesh of the fowl, which contains 0.32 per cent., or from beef-heart, which contains 0.14 per cent. It is soluble in boiling  $H_2O$  and in alcohol, insoluble in ether; crystallizes in brilliant, oblique, rhombic prisms; neutral, tasteless, loses  $aq$  at  $100^\circ$  ( $212^\circ F.$ ); fuses and decomposes at higher temperatures. When long heated with  $H_2O$  or treated with concentrated acids, it loses  $H_2O$ , and is converted into creatinin. Baryta water decomposes it into sarcosin and urea. It is not precipitated by silver nitrate, except when it is in excess and in presence of a small quantity of potassium hydrate. The white precipitate so obtained is soluble in excess of potash, from which a jelly separates, which turns black, slowly at ordinary temperatures, rapidly at  $100^\circ$  ( $212^\circ F.$ ). A white precipitate, which turns

black when heated, is also formed when a solution of creatin is similarly treated with mercuric chlorid and potash.

**Creatinin**— $C_4H_7N_3O$ —113—a product of the dehydration of creatin, is a normal and constant constituent of the urine and amniotic fluid, and also exists in the blood and muscular tissue.

It crystallizes in oblique, rhombic prisms, soluble in  $H_2O$  and in hot alcohol, insoluble in ether. It is a strong base, has an alkaline taste and reaction; expels  $NH_3$  from the ammoniacal salts, and forms well-defined salts, among which is the double chlorid of zinc and creatinin,  $(C_4H_7N_3O)_2ZnCl_2$ , obtained in very sparingly soluble, oblique prismatic crystals, when alcoholic solutions of creatinin and zinc chlorid are mixed.

The quantity of creatinin eliminated is slightly greater than that of uric acid, 0.6–1.3 gram (9.25–20 grains) in 24 hours. It is not increased by muscular exercise, but is diminished in progressive muscular atrophy. It is obtained from the urine by precipitation with zinc chlorid.

**Xanthin**—*Xanthic acid*—*Uric acid*— $C_5H_4N_4O_2$ —152—occurs in a rare form of urinary calculus; in the pancreas, spleen, liver, thymus, and brain of mammals and fishes; and in human urine after the use of sulphur baths or inunctions.

It is an amorphous, yellowish-white powder: very slightly soluble in cold  $H_2O$ . If dissolved in  $HNO_3$  and the solution evaporated, xanthin leaves a yellowish residue, which turns reddish-yellow on the addition of potash solution, and violet-red when heated.

Xanthin calculi vary in size from that of a pea to that of a pigeon's egg. They are rather hard, brownish-yellow, smooth, shining, and made up of well-defined, concentric layers. Their broken surfaces assume a waxy polish when rubbed.

**Hypoxanthin**—**Sarcin**— $C_5H_4N_4O$ —136—occurs in the spleen, muscular tissue, thymus, suprarenal capsules and brain of mammals; in the liver in acute yellow atrophy; and in the blood and urine in leucocythæmia. It may be obtained from the mother liquor of the preparation of creatin (*q.v.*).

It forms nodular masses; soluble in 300 parts of cold, and 78 parts of boiling  $H_2O$ . It is produced from uric acid or from xanthin by the action of sodium amalgam, and when oxidized by  $HNO_3$  it yields xanthin.

**Guanin**— $C_5H_5N_5O$ —151—occurs in guano, in the excrements of the lower animals, and in the pancreas, lungs, and liver of certain mammalians. It is a white or yellowish, amorphous, odorless and tasteless solid; almost insoluble in  $H_2O$ , alcohol and ether; readily soluble in acids and alkalies, with which it forms compounds.

**Carnin**— $C_7H_7N_4O_3 + H_2O$ —196+18—is obtained from Liebig's

meat extract in chalky, microscopic crystals, readily soluble in warm  $H_2O$ . It forms compounds with acids and alkalies, similar to those of hypoxanthin.

### AZOPARAFFINS—NITRILS—CYANOGEN COMPOUNDS.

These substances may be considered either as compounds of the univalent radical cyanogen,  $(Civ N)$ ; or as paraffins,  $C_nH_{2n+2}$ , in which three atoms of hydrogen have been replaced by a trivalent N atom, hence azoparaffins; or as nitrils, compounds of N with the trivalent radicals  $C_nH_{2n-1}$ .

Dicyanogen— $CN_2$ —52—is prepared by heating mercuric cyanid. It is a colorless gas; has a pronounced odor of bitter almonds; sp. gr. 1.8064 A.; burns in air with a purple flame, giving off N and  $CO_2$ . It is quite soluble in  $H_2O$ , the solution turning brown in air.

It has a very deleterious action upon both animal and vegetable life, even when largely diluted with air.

Hydrogen cyanid—*Cyanogen hydrid*—Hydrocyanic acid—Prussic acid— $\begin{matrix} CH \\ H \end{matrix}$ —27—exists ready formed in the juice of *cassava*,

and is formed by the action of  $H_2O$  upon bitter almonds, cherry-laurel leaves, etc. It is also formed in a great number of reactions: by the passage of the electric discharge through a mixture of acetylene and N; by the action of chloroform on  $NH_3$ ; by the distillation of, or the action of  $HNO_3$  upon many organic substances; by the decomposition of cyanids.

It is always prepared by the decomposition of a cyanid or a ferrocyanid. Usually by acting upon potassium ferrocyanid with dilute sulphuric acid, and distilling. Its preparation in the pure form is an operation attended with the most serious danger, and should only be attempted by those well trained in chemical manipulation. For medical uses a very dilute acid is required; the acid hydrocyanicum dil. (U. S., Br.) contains, if freshly and properly prepared, two per cent. of anhydrous acid. That of the French Codex is much stronger—ten per cent.

The pure acid is a colorless, mobile liquid, has a penetrating and characteristic odor; sp. gr. 9.7058 at  $7^\circ$  ( $44.6^\circ F.$ ); crystallizes at  $-15$  ( $5^\circ F.$ ); boils at  $26.5$  ( $79.7^\circ F.$ ); is rapidly decomposed by exposure to light. The dilute acid of the U. S. P. is a colorless liquid, having the odor of the acid; faintly acid, the reddened litmus returning to blue on exposure to air; sp. gr. 0.997; 10 grams of the acid should be accurately neutralized by 1.27 gram of silver nitrate. The dilute acid deteriorates on exposure to light, although more slowly than the concentrated; a trace of phosphoric acid added to the solution retards the decomposition.

Most strong acids decompose HCN. The alkalis enter into double decomposition with it to form cyanids. It is decomposed by Cl and Br, with formation of cyanogen chlorid or bromid. Nascent H converts it into methylamin.

**Analytical Characters.**—(1.) With silver nitrate a dense, white ppt. ; which is not dissolved on addition of  $\text{HNO}_3$  to the liquid, but dissolves when separated and heated with concentrated  $\text{HNO}_3$ ; soluble in solutions of alkaline cyanids or hyposulphites. (2.) Treated with  $\text{NH}_4\text{HS}$ , evaporated to dryness, and ferric chlorid added to the residue ; a blood-red color. (3.) With potash and then a mixture of ferrous and ferric sulphates : a greenish ppt., which is partly dissolved with a deep blue color by HCl. (4.) Heated with a dilute solution of picric acid and then cooled ; a deep red color. (5.) Moisten a piece of filter paper with a freshly prepared alcoholic solution of guaiac ; dip the paper into a very dilute solution of  $\text{CuSO}_4$ , and, after drying, into the liquid to be tested. In the presence of HCN it assumes a deep blue color.

**Toxicology.**—Hydrocyanic acid is a violent poison, whether it be inhaled as vapor, or swallowed, either in the form of dilute acid, of soluble cyanid, or of the pharmaceutical preparations containing it, such as oil of bitter almonds and cherry-laurel water ; its action being more rapid when taken by inhalation or in aqueous solution than in other forms. When the medicinal acid is taken in poisonous dose, its lethal effect may seem to be produced instantaneously ; nevertheless, several respiratory efforts usually are made after the victim seems to be dead, and instances are not wanting in which there was time for considerable voluntary motion between the time of the ingestion of the poison and unconsciousness. In the great majority of cases the patient is either dead or fully under the influence of the poison on the arrival of the physician, who should, however, not neglect to apply the proper remedies if the faintest spark of life remain. Chemical antidotes are, owing to the rapidity of action of the poison, of no avail, although possibly chlorin, recommended as an antidote by many, may have a chemical action on that portion of the acid already absorbed. The treatment indicated is directed to the maintenance of respiration ; cold douche, galvanism, artificial respiration, until elimination has removed the poison. If the patient survive an hour after taking the poison, the prognosis becomes very favorable ; in the first stages it is exceedingly unfavorable, unless the quantity taken has been very small.

In cases of death from hydrocyanic acid a marked odor of the poison is almost always observed in the apartment and upon opening the body, even several days after death. In cases of

suicide or accident, the vessel from which the poison has been taken will usually be found in close proximity to the body, although the absence of such vessel is not proof that the case is necessarily one of homicide.

Notwithstanding the volatility and instability of the poison, its presence has been detected two months after death, although the chances of separating it are certainly the better the sooner after death the analysis is made. The search for hydrocyanic acid is combined with that for phosphorus; the part of the distillate containing the more volatile products is examined by the tests given above. It is best, when the presence of free hydrocyanic acid is suspected, to distil at first without acidulating. In cases of suspected homicide by hydrocyanic acid the stomach should never be opened until immediately before the analysis.

**Cyanids.**—The most important of the metallic cyanids are those of K and Ag (see pp. 190, 193).

The hydrocyanic ethers of the univalent alcoholic radicals are called nitrils, and are frequently the starting-points from which other organic products are obtained.

They are produced :

1.) By distilling a mixture of potassium cyanid and the potassium salt of the corresponding monosulphate of the alcoholic radical :

Potassium cyanid. Potassium ethylsulphate. Ethyl cyanid. Dipotassic sulphate.

2.) By complete dehydration, by the action of  $\text{P}_2\text{O}_5$ , of the ammoniacal salt of the corresponding acid, or of its amid :

Ammonium acetate.

Methyl cyanid.

Acetamid.

Acetonitril.

3.) By the action of the chlorids of the acid radicals upon silver cyanate :

Silver cyanate.

Acetyl chlorid.

Methyl cyanid.

The nitrils combine with nascent hydrogen to form the corresponding amins :

Acetonitril.

Ethylamin.

Hydrating agents convert the nitrils into ammonia and the corresponding acid :

Sulphuric acid, or sulphur trioxid, converts the nitrils into sulpho-acids and monoammonic sulphate :

Isomeric with the nitrils are substances known as **isocyanids**, **carbylamins** or **carbamins**, which are formed :

1.) By the action of a primary monamin on chloroform in the presence of caustic potash :

2.) By the action of the iodoparaffins on silver cyanid :

The difference in the constitution of the two classes of bodies is due to the N being trivalent in the nitril, and quinquivalent in the carbylamin :

The isocyanids do not yield ammonia and an acid by the action of hydrating agents, but are converted into formic acid and a primary amin :

The nitrils and carbamins combine with the hydracids to form crystalline salts, decomposable by water. The latter much more energetically than the former. They are all volatile liquids : the nitrils having ethereal odors when pure, the isocyanids odors which are very powerful and disagreeable.

**Cyanogen chlorids.** — Two polymeric chlorids are known. **Gaseous cyanogen chlorid**— $\text{CNCl}$ —is formed by the action of Cl upon anhydrous hydrocyanic acid or upon mercuric cyanid in the dark. It is a colorless gas, intensely irritating and poisonous. **Solid cyanogen chlorid**— $\text{C}_3\text{N}_3\text{Cl}_3$ —is formed, as a crystalline solid, when anhydrous hydrocyanic acid is acted upon by Cl in sunlight. It fuses at  $140^\circ \text{C}$ . ( $284^\circ \text{F}$ .).

**Cyanic acid**—*Cyanogen hydrate*— $\text{CN} \begin{array}{c} \diagup \\ \text{H} \end{array} \text{O}$ —43—does not exist in nature. It is obtained by calcining the cyanids in presence of an oxidizing agent : or by the action of dicyanogen upon solutions of

the alkalis or alkaline carbonates; or by the distillation of cyanuric acid.

It is a colorless liquid; has a strong odor, resembling that of formic acid; its vapor is irritating to the eyes, and it produces vesication when applied to the skin. It is soluble in water. When free it is readily changed by exposure to air into an isomere, *cyamelid*.

The acid forms salts and ethers which constitute two isomeric series, indicating the existence of two acids, the *normal*, having the constitution  $\text{N} \equiv \text{C}-\text{OH}$ , and the *iso*, having the constitution  $\text{O} = \text{C} = \text{N}-\text{H}$ .

Ammonium isocyanate  $\text{O} = \text{C} = \text{N}-\text{NH}_4$  is converted into urea by heat.

**Cyanuric acid**— $\text{C}_3\text{N}_3\text{H}_3\text{O}_3$ —is a polymere of cyanic acid, formed by the action of heat or of Cl upon urea. It forms colorless crystals, sparingly soluble in  $\text{H}_2\text{O}$ , the solutions odorless, almost tasteless, and feebly acid. It is a tribasic acid. It is very stable and may be dissolved in strong  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$  without suffering decomposition.

**Fulminic acid**— $\text{C}_2\text{N}_2\text{H}_2\text{O}_2$ —is a bibasic acid whose Ag and Hg salts are formed by the action of nitrous acid upon alcohol in the presence of the salts of Ag and Hg. These are the *fulminating powders* used in the manufacture of percussion caps.

**Fulminuric acid**— $\text{C}_3\text{N}_3\text{H}_3\text{O}_3$ —metamerie with cyanuric acid, is a bibasic acid, formed by the action of a metallic chlorid upon a solution of mercuric fulminate.

**Thiocyanic acid**—**Sulphocyanic acid**—*Cyanogen sulphhydrate*— $\begin{smallmatrix} \text{CN} \\ \diagup \\ \text{H} \end{smallmatrix} \text{S}$ —59—bears the same relation to cyanic acid that  $\text{CS}_2$  does to  $\text{CO}_2$ . It is obtained by the decomposition of its salts, which are obtained by boiling a solution of the cyanid with S; by the action of dicyanogen upon the metallic sulphid; and in several other ways.

The free acid is a colorless liquid; crystallizes at  $-12.5$  ( $9.5$  F.); boils at  $102.5$  ( $216.5$  F.); acid in reaction. The prominent reaction of the acid and of its salts is the production of a deep red color with the ferric salts; the color being discharged by solution of mercuric chlorid, but not by HCl.

Sulphocyanic acid exists in human saliva in combination, probably with sodium. The free acid is actively poisonous and its salts were formerly supposed to be so also. It is probable, however, that much of the deleterious action of the potassium salt—that usually experimented with—is due as much to the metal as to the acid.

**Cyanamid**— $\text{CN},\text{NH}_2$ —is produced by the action of gaseous cyanogen chlorid upon ammonia:  $\text{CNCl} + 2\text{NH}_3 = \text{NH}_4\text{Cl} +$

$\text{CN}, \text{NH}_2$ . It forms colorless crystals, soluble in water, alcohol or ether. Corresponding to it are substituted cyanamids, which may be formed by substituting a primary amin for ammonia in the above-mentioned method of preparation:  $\text{CNCl} + 2\text{NH}_2\text{CH}_3 = \text{NH}_3, \text{CH}_3, \text{Cl} + \text{CN}, \text{NHCH}_3$ .

**Metallocyanids.**—The radical cyanogen, besides combining with metallic elements to form true cyanids, in which the radical  $(\text{CN})$  enters as a univalent atom, is capable of combining with certain metals (notably those of the iron and platinum groups) to form complex radicals. These combining with  $\text{H}$ , form acids, and with basic elements form salts in which the analytical reactions of the metallic element entering into the radical are completely masked. Of these **metallocyanids** the best known are those in which iron enters into the radical. As iron is capable of forming two series of compounds, in one of which the single atom  $\text{Fe}$  enters in its bivalent capacity, and in the other of which the hexavalent double atom  $(\text{Fe}_2)^{\text{vi}}$  is contained: so uniting with cyanogen, iron forms two ferrocyanogen radicals:  $[(\text{CN})_6\text{Fe}]^{\text{iv}}$ , **ferrocyanogen**, and  $[(\text{CN})_{12}(\text{Fe}_2)^{\text{vi}}]^{\text{vi}}$  **ferricyanogen**; each of which unites with hydrogen to form an acid, corresponding to which are numerous salts:  $(\text{C}_6\text{N}_6\text{Fe})\text{H}_4$ , **hydroferrocyanic acid**, **tetra-basic**; and  $(\text{C}_{12}\text{N}_{12}\text{Fe}_2)\text{H}_6$ , **hydroferricyanic acid**, **hexabasic** (see potassium and iron salts).

### SULPHUR DERIVATIVES OF THE PARAFFINS.

Sulphur and oxygen, being equal in valence, may replace each other in organic compounds as, for instance, in sulphocyanic acid  $\text{CNSH}$ , corresponding to cyanic  $\text{CNOH}$ .

There exist many derivatives of the paraffins in which  $\text{S}$  thus takes the place of  $\text{O}$ . Thus:

**Methyl sulphids.**—Three are known. The **monosulphid**,  $(\text{CH}_3)_2\text{S}$ , is a colorless liquid, boils at  $41^\circ$  ( $105^\circ \cdot 8 \text{ F.}$ ), has a very disagreeable odor, as have all the alcoholic sulphids and sulphydrates. It is formed by the action of gaseous methyl chlorid on potassium monosulphid. The **bisulphid**,  $(\text{CH}_3)_2\text{S}_2$ , is similarly formed from

potassium bisulphid, and is a colorless liquid, boiling at  $116-118^{\circ}$  ( $240.8-244.4^{\circ}$  F.). The trisulphid  $(\text{CH}_3)_2\text{S}_3$ , is formed in the same way from potassium pentasulphid, and boils at  $200^{\circ}$  ( $392^{\circ}$  F.).

**Ethyl sulphids** are formed in the same manner as the methyl compounds, and have the same constitution.

**Methyl hydrosulphid—Methyl mercaptan— $\text{H}.\text{CH}_3\text{SH}$** —is a very offensive liquid formed by distilling together calcium methylsulphate and potassium hydrosulphid.

**Ethyl sulphhydrate—Thioalcohol—Mercaptan— $\text{CH}_3.\text{CH}_5\text{SH}$** —is best prepared by treating alcohol with  $\text{H}_2\text{SO}_4$ , as in the preparation of sulphovinic acid (*q. v.*); mixing the crude product with excess of potash; separating from the crystals of potassium sulphate; saturating with  $\text{H}_2\text{S}$ ; and distilling.

It is a mobile, colorless liquid; sp. gr. 0.8325; has an intensely disagreeable odor, combined of those of garlic and  $\text{H}_2\text{S}$ ; boils at  $36.2$  ( $97.2^{\circ}$  F.); ignites readily and burns with a blue flame; may be readily frozen by the cold produced by its own evaporation; neutral in reaction; sparingly soluble in  $\text{H}_2\text{O}$ , soluble in all proportions in alcohol and ether; dissolves I, S and P.

Potassium and sodium act with mercaptan as with alcohol, replacing the extra-radical hydrogen. In its behavior toward the oxids it more closely resembles the acids than the alcohols, being capable even of entering into double decomposition to form salts, called **sulphethyldates** or **mercaptids**. Its action with mercuric oxid is characteristic, forming a white, crystalline sulphid of ethyl and mercury:

When a mixture of one molecule of a mercaptan with two molecules of an aldehyde is treated with dry  $\text{HCl}$ , a stable compound is produced which is called a **mercaptal**, being an acetal whose O is replaced by S.

If the reaction take place with an acetone, in place of with an aldehyde, a **mercaptol** is produced, which differs from the mercaptal in that an alcoholic radical is substituted for the remaining H atom of the methane:

**Ethyl mercaptol— $(\text{CH}_3)_2\text{C} = (\text{SC}_2\text{H}_5)$** —is formed as one of the steps in the manufacture of sulphonal. It is produced by the action of dry  $\text{HCl}$  upon a mixture of acetone and ethylmercaptan, or upon a mixture of sodium ethylthiosulphate,

$C_2H_5SO_2ONa$ , and acetone. It is a mobile liquid, whose odor is not disagreeable. When heated it begins to boil at about  $80^\circ$  ( $176^\circ$  F.) and the temperature rises rather regularly to  $192^\circ$  ( $377.6^\circ$  F.).

Oxidizing agents act readily upon the mercaptals and mercaptols to produce compounds called **sulphones**, whose constitution is represented by one of the three following formulæ, in which R is a univalent alcoholic radical :

**Sulphonal--Diethylsulphondimethylmethane**— $\begin{array}{c} CH_3 \\ \backslash \\ C \\ / \\ CH_3 \end{array} \begin{array}{c} SO_2C_2H_5 \\ SO_2C_2H_5 \end{array}$

—is obtained by the oxidation of ethyl-mercaptol, prepared as above described, by potassium permanganate. It crystallizes in thick, colorless prisms, difficultly soluble in cold water or alcohol, readily soluble in hot water or alcohol, and in ether, benzene and chloroform. It fuses at  $130-131^\circ$  ( $266-267.8^\circ$  F.), and boils at  $300^\circ$  ( $572^\circ$  F.), suffering partial decomposition. It dissolves in concentrated  $H_2SO_4$ , and is decomposed by the acid when heated, but may be precipitated from the cold solution unchanged by dilution with  $H_2O$ . Nitric acid does not affect it, even when heated. It is not attacked by Br, by caustic alkalies or by nascent H.

**Ichthyol**—is the Na salt of a complex sulphonic acid, having the empirical formula  $C_{22}H_{36}S_3Na_2O_6$ , obtained by the distillation and purification of an ozocerite-like mineral deposit. It is a dark brown, pitch-like mass having a disagreeable odor.

## COMPOUNDS OF THE ALCOHOLIC RADICALS WITH OTHER ELEMENTS.

**Phosphins, arsins, and stibins**, are compounds resembling the amins in constitution, in which the N is replaced by P, As, or Sb. Like the amins, they may be primary, secondary, or tertiary :

There also exist compounds containing P, As, or Sb, which are similar in constitution to the hydrates and salts of ammonium, and of the compound ammoniums :

Most of these compounds, which are very numerous, are as yet only of theoretic interest. One of them, however, is deserving of notice here :

Dimethyl Arsin,  $\begin{matrix} \text{CH}_3 \\ \text{CH}_3 \\ \text{H} \end{matrix} \left\{ \text{As}-106 \right.$ —which may be considered as

being the hydrid of the radical  $[\text{As}(\text{CH}_3)_2]$ , does not exist as such. There is, however, a liquid known as the **fuming liquor of Cadet**, or **alkarsin**, which is obtained by distilling a mixture of potassium acetate and arsenic trioxid. This liquid contains the oxid of the above radical, and a substance which ignites on contact with air, and which consists of the same radical united to itself,  $2[\text{As}(\text{CH}_3)_2]$ . This radical, called **cacodyle** (*κακός* = evil), is capable of entering into a great number of other combinations. Cacodyle and its compounds are all exceedingly poisonous, especially the cyanid, an ethereal liquid, very volatile, the presence of whose vapor in inspired air, even in minute traces, produces symptoms referable both to arsenic and to hydrocyanic acid.

**Organo-metallic substances** are compounds of the alcoholic radicals with metals. They are very numerous, usually obtained by the action of the iodid of the alcoholic radical upon the metallic element, in an atmosphere of H. They are substances which, although they have been put to no uses in the arts or in medicine, have been of great service in chemical research. As typical of this class of substances we may mention :

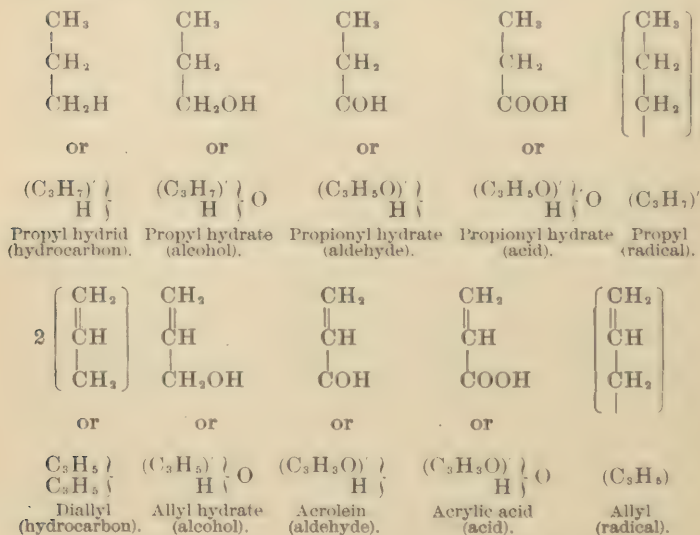

Zinc-ethyl —  $\begin{matrix} \text{C}_2\text{H}_5 \\ \text{C}_2\text{H}_5 \end{matrix} \left\{ \text{Zn}-123 \right.$ —obtained by heating at  $130^\circ$  ( $266^\circ$  F.) in a sealed tube a mixture of perfectly dry zinc amalgam with ethyl iodid; the contents of the tube are then distilled in an atmosphere of coal-gas, or H, and the distillate collected in a receiver, in which it can be sealed by fusion of the glass without contact with air.

It is a colorless, transparent, highly refracting liquid : sp. gr. 1.182 ; boils at  $118^\circ$  ( $244.4^\circ$  F.). On contact with air it ignites and burns with a luminous flame, bordered with green, and gives off dense clouds of zinc oxid, a property which renders it very dangerous to handle. On contact with  $\text{H}_2\text{O}$  it is immediately decomposed into zinc hydrate and ethyl hydrid. It is chiefly useful as an agent by which the radical ethyl can be introduced into organic molecules.

## ALLYLIC SERIES.

The compounds heretofore considered may be derived more or less directly from the saturated hydrocarbons; in the derivatives, as in the hydrocarbons, the valences of the C atoms are all satisfied, and ~~that~~ in the simplest and most complete manner, two neighboring C atoms always exchanging a *single* valence. There exist, however, other compounds containing less H in proportion to C than those already considered, and yet resembling them in being monoatomic. These compounds have usually been considered as *non-saturated*, because all the *possible* valences are not satisfied, and the substances are therefore capable of forming products of *addition*, while the *saturated* compounds can only form products of *substitution*.

In this sense the substances composing this series are non-saturated, but they are not so in the sense that they contain C or other atoms whose valences are not satisfied. The following formulæ indicate the constitution of the substances of this series, and their relation to those of the previous one. It will be observed that in the allyl compounds, two neighboring C atoms exchange *two* valences :

Diallyl— $\begin{array}{c} \text{C}_3\text{H}_5 \\ | \\ \text{C}_3\text{H}_5 \end{array}$ —82—formerly known as *allyl*, is obtained by the action of sodium upon allyl iodid, and is not, as its empirical

formula would seem to indicate, a superior homologue of acetylene and allylene (*q.v.*).

It is a colorless liquid, having a peculiar odor, somewhat resembling that of horseradish; boils at  $59^{\circ}$  ( $138.2^{\circ}$  F.); sp. gr. 0.684 at  $14^{\circ}$  ( $57.2^{\circ}$  F.).

**Vinyl hydrate—Vinyl alcohol**— $\text{C}_2\text{H}_3\text{O}$ — $\left\{ \begin{array}{l} \text{O} \end{array} \right.$ —is produced by distilling vinyl sulphuric acid,  $(\text{C}_2\text{H}_3)\text{H.SO}_4$ , formed by the action of  $\text{H}_2\text{SO}_4$  on acetylene, with  $\text{H}_2\text{O}$ . It is an unstable liquid, having a very pungent odor.

**Allyl hydrate—Allylic alcohol**— $\text{C}_3\text{H}_5\text{O}$ — $\left\{ \begin{array}{l} \text{O} \end{array} \right.$ —58—may be obtained by the action of sodium upon dichlorhydrin in ethereal solution; or by heating four parts of glycerin with one part of crystallized oxalic acid.

Allylic alcohol is a colorless, mobile liquid; solidifies at  $-54^{\circ}$  ( $-65.2^{\circ}$  F.); boils at  $97^{\circ}$  ( $206.6^{\circ}$  F.); sp. gr. 0.8507 at  $25^{\circ}$  ( $77^{\circ}$  F.); soluble in  $\text{H}_2\text{O}$ ; has an odor resembling the combined odors of alcohol and essence of mustard; burns with a luminous flame.

Allyl alcohol is isomeric with propylic aldehyde and with acetone. Being an unsaturated compound, it is capable of forming products of addition with Cl, Br and I, etc., which are isomeric or identical with products of substitution obtained by the action of the same elements upon glycerin. Oxidizing agents convert it first into acrolein, acrylic aldehyde,  $\text{C}_3\text{H}_4\text{O}$ , and finally into acrylic acid. It does not combine readily with H, but in the presence of nascent H combination takes place slowly, with formation of propylic alcohol.

**Allyl oxid—Allylic ether**— $\text{C}_3\text{H}_5\text{O}$ — $\left\{ \begin{array}{l} \text{C}_3\text{H}_5 \\ \text{C}_3\text{H}_5 \end{array} \right.$ — $\left\{ \begin{array}{l} \text{O} \end{array} \right.$ —98—exists in small quantities in crude essence of garlic. It is obtained as a colorless liquid, having an alliaceous odor; insoluble in  $\text{H}_2\text{O}$ ; boiling at  $82^{\circ}$  ( $179.6^{\circ}$  F.), by a number of reactions, but best by the action of allyl iodid upon sodium-allyl oxid.

**Allyl sulphid—Essence of garlic**— $\text{C}_3\text{H}_5\text{S}$ — $\left\{ \begin{array}{l} \text{C}_3\text{H}_5 \\ \text{C}_3\text{H}_5 \end{array} \right.$ — $\left\{ \begin{array}{l} \text{S} \end{array} \right.$ —114—is obtained by the action of an alcoholic solution of potassium sulphid upon allyl iodid; also as a constituent of the volatile oil of garlic, by macerating garlic, or other related vegetables, in water, and distilling. Crude essence of garlic is thus obtained as a heavy, fetid, brown oil; this is purified by redistillation below  $140^{\circ}$  ( $284^{\circ}$  F.); contact with potassium, and subsequent redistillation from calcium chlorid.

It is a colorless, transparent oil; lighter than  $\text{H}_2\text{O}$ , sparingly soluble in  $\text{H}_2\text{O}$ , very soluble in alcohol and ether; boils at  $140^{\circ}$  ( $280^{\circ}$  F.); has an intense odor of garlic. It does not exist naturally in the plant, but is formed during the process of extraction

by the action of  $H_2O$ , probably in a manner similar to that in which essence of mustard is formed under similar circumstances. It is to the formation of allyl sulphid, which is highly volatile, that garlic owes the odor which it emits.

**Allyl chlorid**— $C_3H_5Cl$ —a colorless liquid, boils at  $46$  ( $114.8$  F.), has an irritating odor; formed by slowly adding  $PCl_3$  to allyl alcohol.

**Allyl bromid**— $C_3H_5Br$ —a liquid boiling at  $71$  ( $159.8$  F.), obtained in the same manner as the chlorid, using  $PBr_3$ .

**Allyl iodid**— $C_3H_5I$ —a colorless liquid having a peculiar odor; boils at  $101.5$  ( $214.7$  F.); insoluble in  $H_2O$ ; obtained by carefully mixing allyl alcohol, red P, and I, and distilling after 24 hours.

**Allyl tribromid**— $(C_3H_5Br)_3$ —a colorless liquid, very soluble in ether, boiling at  $217$  ( $422$  F.), solidifying at  $-10$  ( $14$  F.); obtained by acting upon allyl iodid with  $2\frac{1}{2}$  times its weight of Br. Has been recommended as a nervous sedative.

**Allyl sulphocyanate**—*Essential oil of mustard*—**Oleum sinapis volatile** (U. S.)— $\left. \begin{matrix} CN \\ C_3H_5 \end{matrix} \right\} S-99$ .—If the seeds of white or black mustard be strongly expressed, a bland, neutral oil is obtained, which resembles rape-seed and colza oils in its physical properties, and in being composed of the glycerids of stearic, oleic, and erucic acids. The cake remaining after the expression of this oil from *black mustard*, or the black-mustard seeds themselves, pulverized and moistened with  $H_2O$ , gives off a strong, pungent odor. If the  $H_2O$  be now distilled, a volatile oil passes over with it, which is the crude essential oil of mustard.

In practice the powdered cake of black-mustard seeds, from which the fixed oil has been expressed, is digested with  $H_2O$  for 24 hours, after which the  $H_2O$  is distilled as long as any oily matter passes over; the oil is collected, dried by contact with calcium chlorid, and redistilled. Essence of mustard may also be obtained synthetically by the action of allyl bromid or iodid upon potassium sulphocyanate, or by the action of allyl iodid upon silver sulphocyanate.

This essence does not exist preformed in the mustard, but results from the decomposition of a peculiar constituent of the seeds, potassium myronate, determined by cryptolytic action set up by another constituent, myrosin, in the presence of  $H_2O$ .

**Potassium myronate** exists only in appreciable quantity in the black variety of mustard, from which it may be obtained in the shape of short prismatic crystals, transparent, odorless, bitter; very soluble in  $H_2O$ , sparingly so in alcohol.

**Myrosin** is a nitrogenized cryptolite, existing in the white as well as in the black mustard, and in other seeds. It may be obtained from white mustard seeds, in an impure form, by extrac-

tion with cold  $H_2O$ , filtering and evaporating the solution at a temperature below  $40^\circ$  ( $104^\circ F.$ ); the syrupy fluid so obtained is precipitated with alcohol, the precipitate washed with alcohol, redissolved in  $H_2O$ , and the solution evaporated below  $40^\circ$  ( $104^\circ F.$ ) to dryness.

At temperatures above  $40^\circ$  ( $104^\circ F.$ ) myrosin becomes coagulated and incapable of decomposing potassium myronate, a change which is also produced by contact with acetic acid. As the rubefacient and vesicant actions of mustard when moistened with  $H_2O$ , are due to the production of allyl sulphocyanate, neither vinegar, acetic acid, nor heat greater than  $40^\circ$  ( $104^\circ F.$ ) should be used in the preparation of mustard cataplasms.

Pure allyl sulphocyanate is a transparent, colorless oil; sp. gr. 1.015 at  $20^\circ$  ( $68^\circ F.$ ); boils at  $143^\circ$  ( $289.4^\circ F.$ ); has a penetrating, pungent odor, sparingly soluble in  $H_2O$ , very soluble in alcohol and ether. When exposed to the light it gradually turns brownish-yellow and deposits a resinoid material. When applied to the skin it produces rubefaction, quickly followed by vesication.

## ACIDS AND ALDEHYDES OF THE ACRYLIC SERIES.

These substances bear the same relation to the alcohols of the allyl series that the volatile fatty acids and the corresponding aldehydes bear to the ethylic series of alcohols.

The acids of this series differ from those containing the same number of C atoms in the formic series, by containing two atoms of H less: they are readily converted into acids of the formic series by the action of potassium hydrate in fusion.

**Acrylic acid**— $C_3H_3O \begin{smallmatrix} O \\ H \end{smallmatrix} \backslash O$ —72—is obtained by oxidation of acrolein by silver oxid, and is formed in a number of other reactions. It is a colorless, highly acid liquid; has a penetrating odor; solidifies at  $7^\circ$  ( $44.6^\circ F.$ ); boils at  $140^\circ$  ( $284^\circ F.$ ). Nascent H unites with it to form propionic acid. It forms crystalline salts and ethers.

**Acrylic aldehyde—Allylic aldehyde—Acrolein**— $C_3H_3O \begin{smallmatrix} O \\ H \end{smallmatrix} \backslash$ —56.—

When the fats and fixed oils are decomposed by heat, a disagreeable, irritating odor is produced, which is due to the formation of acrolein by the dehydration of the glycerin contained in the fatty material. Acrolein may be obtained by heating glycerin with strong  $H_2SO_4$ , or with hydropotassic sulphate. Glycerin is the alcohol (hydrate) of a radical having the same composition as allyl, but so differing from it in constitution as to be trivalent in place of univalent.

Acrolein is a colorless, limpid liquid; lighter than  $\text{H}_2\text{O}$ : boils at  $52.4$  ( $126.3$  F.); sparingly soluble in  $\text{H}_2\text{O}$ , more soluble in alcohol; very volatile; its vapor is very pungent and irritating. When freshly prepared it is neutral in reaction, but on contact with air it rapidly becomes acid by oxidation. For the same reason it does not keep well, even in closed vessels; on standing it deposits a flocculent material, which has been called *disocryl*, while at the same time formic, acetic, and acrylic acids are formed. Oxidizing agents convert it into acrylic acid, or, if they be energetic, into a mixture of formic and acetic acids. The caustic alkalies produce from it resinoid substances similar to those formed from acetic aldehyde. With  $\text{NH}_3$  it forms a crystalline, odorless compound, which behaves as a base.

Acrolein is formed whenever glycerin, or any substance containing it or its compounds with the fatty acids, is heated to a temperature sufficient to effect its decomposition; for this reason and because of the irritating action of the acrolein, the heavy petroleum-oils are preferable to those of vegetable or animal origin for the lubricating of machinery operated in enclosed places.

Crotonic acid— $\text{C}_4\text{H}_5\text{O} \left\{ \begin{array}{l} \text{C}_4\text{H}_5\text{O} \\ \text{H} \end{array} \right\} \text{O}$ —86—was first obtained from croton-oil, *oleum tiglii* (U. S.), *oleum crotonis* (Br.), in which it exists in combination with glycerin, and accompanied by the glycerin ethers of several other fatty acids; it is, however, neither the vesicant nor the purgative principle of the oil. It may be obtained by saponification of croton-oil, or, better, by the action of potassium hydrate upon allyl cyanid.

It is an oily liquid; solidifies at  $-5$  ( $23$  F.); acrid in taste; gives off highly irritating vapors at temperatures slightly above  $0$  ( $32$  F.). When taken internally it acts as an irritant poison.

An acid obtained by oxidation of crotonic aldehyde is probably an isomere, as it is in the form of crystals at ordinary temperatures, and only fuses at  $73^\circ$  ( $163.4$  F.).

Crotonic aldehyde— $\text{C}_4\text{H}_6\text{O} \left\{ \begin{array}{l} \text{C}_4\text{H}_6\text{O} \\ \text{H} \end{array} \right\}$ —70.—If aldehyde,  $\text{H}_2\text{O}$ , and  $\text{HCl}$  be mixed together at a low temperature, and the mixture exposed to diffused daylight for some days, an oily liquid is formed, which, after purification, has the composition  $\text{C}_4\text{H}_8\text{O}_2$ . This substance, known as *aldol*, when exposed to heat, is decomposed into water and crotonic aldehyde:  $\text{C}_4\text{H}_8\text{O}_2 = \text{H}_2\text{O} + \text{C}_4\text{H}_6\text{O}$ .

Crotonic aldehyde is a colorless liquid; boils at  $105$  ( $221$  F.); gives off highly irritating vapors. It bears the same relation to croton chloral that aldehyde does to chloral.

**Angelic acid**— $\text{C}_5\text{H}_7\text{O}_2 \begin{smallmatrix} \text{O} \\ \diagup \\ \text{H} \end{smallmatrix} \text{O}$ —100—exists in angelica root, in the flowers of chamomile, *Anthemis* (U. S.), and in croton-oil.

It crystallizes in colorless prisms, which fuse at  $45.5$  ( $113.9$  F.); boils at  $185$  ( $365$  F.); has an aromatic odor and an acid, pungent taste; sparingly soluble in cold  $\text{H}_2\text{O}$ ; readily soluble in hot  $\text{H}_2\text{O}$ , alcohol, and ether. By the action of heat it is converted into its isomere, methylcrotonic acid,  $\text{C}_4\text{H}_7(\text{CH}_3)\text{O}_2 \begin{smallmatrix} \text{O} \\ \diagup \\ \text{H} \end{smallmatrix} \text{O}$ .

**Oleic acid**—**Acidum oleicum** (U. S.)— $\text{C}_{18}\text{H}_{33}\text{O}_2 \begin{smallmatrix} \text{O} \\ \diagup \\ \text{H} \end{smallmatrix} \text{O}$ —246—exists as its glyceric ether, olein, in most, if not in all the fats and in all fixed oils. It is obtained in an impure form on a large scale as a by-product in the manufacture of candles. This product is, however, very impure. To purify it, it is first cooled to  $0$  ( $32$  F.), the liquid portion collected; cooled to  $-10$  ( $14$  F.), expressed, and the solid portion collected; this is melted and treated with half its weight of massicot; the lead oleate so obtained is dissolved out by ether; the decanted ethereal solution is shaken with  $\text{HCl}$ , the ethereal layer decanted and evaporated, when it leaves oleic acid, contaminated with a small quantity of oxyoleic acid, from which it can be purified only by a tedious process.

Pure oleic acid is a white, pearly, crystalline solid, which fuses to a colorless liquid at  $14$  ( $57.2$  F.); it is odorless and tasteless; soluble in alcohol, ether, and cold  $\text{H}_2\text{SO}_4$ ; insoluble in  $\text{H}_2\text{O}$ ; sp. gr.  $0.808$  at  $19$  ( $66.2$  F.). Neutral in reaction. It can be distilled in vacuo without decomposition, but when heated in contact with air, it is decomposed with formation of hydrocarbons, volatile fatty acids, and sebacic acid. It dissolves the fatty acids readily, forming mixtures whose consistency varies with the proportions of liquid and solid acid which they contain. The solid acid is but little altered by exposure to air, but when liquid it absorbs  $\text{O}$  rapidly, becomes yellow, rancid, acid in reaction, and incapable of solidifying when cooled; these changes take place the more rapidly the higher the temperature.

When heated with a small amount of chlorine, bromine or iodine under pressure to  $270$ – $280$  ( $518$ – $536$  F.) for several hours, oleic acid is converted into a mixture of solid fatty acids containing 70 per cent. of stearic acid.

$\text{Cl}$  and  $\text{Br}$  under ordinary pressure attack oleic acid with formation of products of substitution. If oleic acid be heated with an excess of caustic potassa to  $200$  ( $392$  F.), it is decomposed into palmitic and acetic acids:  $\text{C}_{18}\text{H}_{33}\text{O}_2 + 2\text{KHO} = \text{C}_{16}\text{H}_{31}\text{O}_2\text{K} + \text{C}_2\text{H}_3\text{O}_2\text{K} + \text{H}_2$ ; a reaction which is utilized industrially to obtain hard soaps, palmitates, from olein, which itself only forms soft soaps. Cold  $\text{H}_2\text{SO}_4$  dissolves oleic acid, and deposits it unaltered

on the addition of  $H_2O$ , but if the acid solution be heated it turns brown and gives off  $SO_2$ . Nitric acid oxidizes it energetically, with formation of a number of volatile fatty acids and acids of another series—suberic, adipic, etc. The oleates of the alkali metals are soft, soluble soaps; those of the earthy metals are insoluble in  $H_2O$ , but soluble in alcohol and in ether.

**Elaidic acid** is an isomere of oleic acid, produced by the action upon it of nitrous acid in the preparation of *Unguentum hydrargyri nitratis* (U. S.; Br.). The nitrous fumes formed convert the oleic acid, contained in the oil and lard used, into elaidic acid, which exists in the ointment in combination with mercury.

## SECOND SERIES OF HYDROCARBONS—OLEFINS.

SERIES  $C_nH_{2n}$ .

The terms of this series contain two H atoms less than the corresponding terms of the first series. They differ in constitution in this, that, while in the first series a single valence is exchanged between each two neighboring C atoms, in the second series two valences are exchanged between two of the C atoms:

They are designated as olefins; or, to distinguish them from the terms of the first series, by the terminations *ylene* or *ene*, thus the second is called **ethylene** or **ethene**. They behave as bivalent radicals.

**Ethene—Ethylene—Olefiant gas—Elayl—Heavy carburetted hydrogen—** $\begin{array}{c} CH_2 \\ CH_2 \end{array}$ —28—is formed by the dry distillation of fats, resins, wood, and coal, and is one of the most important constituents of illuminating gas. It is also obtained by the dehydration of alcohol or ether.

It has been obtained synthetically: (1) by passing a mixture of  $H_2S$  and carbon monoxid over iron or copper heated to redness; (2) by heating acetylene in the presence of H, or by the action of nascent H upon copper acetylid; (3) by the action of H upon the chlorid  $C_2Cl_4$ , obtained by the action of Cl upon carbon disulphid. It is prepared in the laboratory by the dehydration of alcohol: a mixture of 4 pts.  $H_2SO_4$  and 1 pt. alcohol is placed in a flask containing enough sand to form a thin paste, and gradually heated to about 170 (338 F.); the gas, which is given off in abundance, is purified by causing it to pass through wash-bottles containing  $H_2O$ , an alkaline solution, and concentrated  $H_2SO_4$ .

Pure ethylene is a colorless gas; tasteless; has a faint odor resembling that of salt water, or an ethereal odor when impure; irrespirable; sparingly soluble in  $H_2O$ , more soluble in alcohol. It burns with a luminous, white flame, and forms explosive mixtures with air and oxygen.

When heated for some time at a dull red heat it is converted into acetylene, ethyl and methyl hydrids, a tarry product, and carbon.

Ethylene readily enters into combination. It unites with H to form ethyl hydrid,  $C_2H_6$ . With O it unites explosively on the approach of a flame, with formation of carbon dioxid and  $H_2O$ .

Oxidizing agents, such as potassium permanganate in alkaline solution, convert it into oxalic acid and  $\text{H}_2\text{O}$ . A mixture of Cl and ethene, in the proportion of two volumes of the former to one of the latter, unite with an explosion on contact with flame, the union being attended with a copious deposition of C and the formation of HCl. Chlorin and ethene, mixed in equal volumes and exposed to diffused daylight, unite slowly, with formation of an oily liquid; **ethene chlorid**,  $\text{C}_2\text{H}_4\text{Cl}_2$ =**Dutch liquid**, to whose formation ethene owes the name *olefiant gas*. By suitable means ethene may also be made to yield chlorinated products of substitution, the highest of which is carbon dichlorid,  $\text{C}_2\text{Cl}_4$ . Br and I also form products of addition and of substitution with ethene. By union with  $(\text{OH})_2$  it forms glycol (*q.r.*). It slowly dissolves in ordinary  $\text{H}_2\text{SO}_4$ , with formation of sulphovinic acid. With fuming  $\text{H}_2\text{SO}_4$  it combines with elevation of temperature and formation of ethionic anhydrid.

When inhaled, diluted with air, ethene produces effects somewhat similar to those of nitrous oxid.

**Pentene**—*Amylene* or *valerene*— $\text{C}_5\text{H}_{10}$ —70—a colorless, mobile liquid, boiling at 39 ( $102.2^\circ \text{F.}$ ); obtained by heating alcohol with a concentrated solution of zinc chlorid.

Its use as an anæsthetic has been suggested.

**Ethene chlorid**—**Bichlorid of ethylene**—**Dutch liquid**— $\begin{array}{c} \text{CH}_2\text{Cl} \\ | \\ \text{CH}_2\text{Cl} \end{array}$ —

99—is obtained by passing a current of ethene through a retort in which Cl is being generated, and connected with a cooled receiver. The distillate is washed with a solution of caustic potassa, afterward with  $\text{H}_2\text{O}$ , and is finally rectified.

It is a colorless, oily liquid, which boils at  $82.5^\circ$  ( $180.5^\circ \text{F.}$ ); has a sweetish taste and an ethereal odor. It is isomeric with the

chlorid of monochlorinated ethyl,  $\begin{array}{c} \text{C}_2\text{H}_4\text{Cl} \\ | \\ \text{Cl} \end{array}$ , which boils at  $64^\circ$  ( $147.2^\circ \text{F.}$ ).

It is capable of fixing other atoms of Cl by substitution for H, and thus forming a series of chlorinated derivatives, the highest of which is  $\text{C}_2\text{Cl}_6$ .

## DIATOMIC ALCOHOLS.

### SERIES $\text{C}_n\text{H}_{2n+2}\text{O}_2$ .

These substances are usually designated as glycols. They are the hydrates of the hydrocarbons of the series  $\text{C}_n\text{H}_{2n}$ , and consist of those hydrocarbons, playing the part of bivalent radicals, united with two groups OH; their general typical formula is then  $\left. \begin{array}{c} (\text{C}_n\text{H}_{2n})'' \\ \text{H}_2 \end{array} \right\} \text{O}_2$ . We have seen (p. 238) that the primary monoatomic

alcohols contain the group of atoms ( $\text{CH}_2\text{OH}$ ), united with  $n(\text{C}_n\text{H}_{2n+1})$ ; the primary glycols are similarly constructed, and consist of twice the group ( $\text{CH}_2\text{OH}$ ), united in the higher terms to  $n(\text{CH}_2)$ . The constitution of the glycols and their relations to the monoatomic alcohols are indicated by the following formulæ:

As the monoatomic alcohols are such by containing in their molecules a group (OH), closely attached to an electro-positive group, and capable of removal and replacement by an electro-negative group or atom, so the glycols are *diatomic* by the fact that they contain two such groups (OH). As the monoatomic alcohols are therefore only capable of forming a single ether with a monobasic acid, the glycols are capable of forming two such ethers:

**Methene glycol**, which would have the composition  $\text{H}_2\text{C} \begin{smallmatrix} \diagup \text{OH} \\ \diagdown \text{OH} \end{smallmatrix}$ , is not known. Its haloid ethers are, however, known. A condensation product corresponding to it exists as **methene dimethylate**,  $\text{H}_2\text{C} \begin{smallmatrix} \diagup \text{OCH}_3 \\ \diagdown \text{OCH}_3 \end{smallmatrix}$ , also called **methylal** and **formal**, as a thin liquid, boiling at  $42^\circ$  ( $107.6^\circ \text{F.}$ ), soluble in alcohol, ether, and water, sp. gr. 0.855; formed by oxidizing methyl alcohol with  $\text{H}_2\text{SO}_4$  and  $\text{MnO}_2$ . It has been used as a medicine.

**Ethene glycol**—**Ethylene glycol** or **Alcohol** or **Hydrate**— $\begin{array}{c} \text{CH}_2\text{OH} \\ | \\ \text{CH}_2\text{OH} \end{array}$   
—62.—This, the best known of the glycols, is prepared by the action of dry silver acetate upon ethylene bromid. The ether so obtained is purified by redistillation, and decomposed by heating for some time with barium hydrate.

It is a colorless, slightly viscous liquid; odorless; faintly sweet; sp. gr. 1.125 at  $0^\circ$  ( $32^\circ \text{F.}$ ); boils at  $197^\circ$  ( $386.6^\circ \text{F.}$ ); sparingly soluble in ether; very soluble in water and in alcohol.

It is not oxidized by simple exposure to air, but on contact with platinum-black it is oxidized to glycolic acid; more energetic oxidants transform it into oxalic acid. Chlorin acts slowly upon glycol in the cold; more rapidly under the influence of heat, producing chlorinated and other derivatives. By the action of dry  $\text{HCl}$  upon cooled glycol, a product is formed, intermediate between

it and ethylene chlorid, a neutral compound—**ethene chlorhydrin**,  $\text{CH}_2\text{OH}$   
 $\begin{array}{c} | \\ \text{CH}_2\text{Cl} \end{array}$ , which boils at  $130^\circ$  ( $266^\circ$  F.).

**Ethene oxid**—**Ethylene oxid**— $(\text{C}_2\text{H}_4)\text{O}$ —44.—This substance, isomeric with aldehyde, is obtained by the action of potassium hydrate upon ethene chlorhydrate.

It is a transparent, volatile liquid; boils at  $13^\circ.5$  ( $54^\circ.3$  F.); gives off inflammable vapors; mixes with  $\text{H}_2\text{O}$  in all proportions. It is capable of uniting directly with  $\text{H}_2\text{O}$  to form glycol; and with  $\text{HCl}$  gas to regenerate ethene chlorhydrin.

**Taurin**— $\text{SO}_3\text{C}_2\text{H}_4\text{N}$ —125—is isomeric with a derivative of glycol, **isethionamid**. It is obtained from ox-bile by boiling with dilute  $\text{HCl}$ ; decanting and concentrating the liquid, separating from the sodium chlorid which crystallizes; evaporating further, and precipitating with alcohol. The deposit is purified by recrystallization from alcohol.

It crystallizes in large, transparent, oblique, rhombic prisms, permanent in air, soluble in  $\text{H}_2\text{O}$ , almost insoluble in absolute alcohol and ether.

Taurin has acid properties and forms salts; it is not attacked by  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , or nitromuriatic acid, but is oxidized by nitrous acid, with formation of  $\text{H}_2\text{O}$ ,  $\text{N}$ , and isethionic acid.

It exists in the animal economy, in the bile in taurocholic acid (*q.v.*); and has also been detected in the intestine and fæces, muscle, blood, liver, kidneys, and lungs. The **pneumic acid**, described as existing in the lung, is taurin. When taken internally, it is eliminated by the urine, not in its own form, but as **taurocarbamic** or **isethionuric acid**,  $\text{C}_3\text{H}_5\text{N}_2\text{SO}_6$ .

### ACIDS DERIVED FROM THE GLYCOLS.

As the acids of the acetic series are obtained from the primary monoatomic alcohols by the substitution of  $\text{O}$  for  $\text{H}_2$  in the characterizing group  $\text{CH}_2\text{OH}$ :

so the diatomic alcohols may, by oxidation, be made to yield acids, formed by the same substitution of  $\text{O}$  for  $\text{H}_2$ . But the glycols differ from the monoatomic alcohols in containing two groups  $\text{CH}_2\text{OH}$ , and they consequently yield two acids, as the substitution occurs in one or both of the alcoholic groups:

A study of these two acids shows them to be possessed of peculiar differences of function. Each of them contains two groups (OH), whose hydrogen is capable of replacement by an acid or alcoholic radical:

They are, therefore, both said to be diatomic. The ability, however, of the two acids to form salts is not the same, for while oxalic acid is capable of forming two salts of univalent metals, and a salt of a bivalent metal with a single molecule of the acid: glycolic acid only forms a single salt of an univalent metal, and two of its molecules are required to form a salt of a bivalent metal: in other words, glycolic acid is monobasic, while oxalic acid is dibasic. It is only that H atom which is contained in the electro-negative group COOH which is replaceable as acid hydrogen, while that of the electro-positive group CH<sub>2</sub>OH is only replaceable, as is the corresponding hydrogen of an alcohol.

In general terms, therefore, the atomicity of an organic acid may be greater than its basicity, the former representing the number of H atoms contained in its molecule which are capable of being displaced by alcoholic radicals, while the latter represents the number of H atoms replaceable by electro-positive elements or radicals, with formation of salts or of ethers.

There may, therefore, be obtained from the glycols, by more or less complete oxidation, two series of acids: those of the first are diatomic and monobasic; those of the second diatomic and dibasic.

## DIATOMIC AND MONOBASIC ACIDS.

### SERIES C<sub>n</sub>H<sub>2n</sub>O<sub>3</sub>.

The acids of this series at present known are:

(Carbonic acid).....C <sub>1</sub> O <sub>2</sub> H <sub>2</sub>	Oxyvaleric acid.....C <sub>5</sub> O <sub>3</sub> H <sub>10</sub>
Glycolic acid.....C <sub>2</sub> O <sub>3</sub> H <sub>4</sub>	Leucic acid.....C <sub>6</sub> O <sub>3</sub> H <sub>12</sub>
Ethylene-lactic acid....C <sub>3</sub> O <sub>3</sub> H <sub>6</sub>	(?) C <sub>11</sub> nanthic acid....C <sub>11</sub> O <sub>3</sub> H <sub>22</sub>
Butylactic acid.....C <sub>4</sub> O <sub>3</sub> H <sub>8</sub>	

The first-named of these acids, although not capable, so far as yet known, of existing in the free state, is widely represented in nature in the shape of its salts, the carbonates. Its position in this series is an anomaly, and at first sight a contradiction, as it is certainly not a monobasic, but a distinctly dibasic acid, or, more properly speaking, would be such were it obtained in a state of purity. It is, however, in this position, as the inferior homologue of glycolic acid, that carbonic acid is most naturally

placed, and the dibasic nature of the latter acid does not present any valid objection to such a position, for, if we consider one term of a series as derivable from its superior homologue by the subtraction of  $\text{CH}_2$ , and if we bear in mind that the basic nature of the hydrogen atom in a group  $\text{OH}$  depends upon its close union with the group  $\text{CO}$  (or with some other electro-negative group), it will become evident that the inferior homologue of glycolic acid must contain two groups  $\text{OH}$  united to one  $\text{CO}$ , and must, therefore, be dibasic:

The other acids of the series are formed: (1.) By the partial oxidation of the corresponding glycol:

(2.) By the combined action of water and silver oxid upon the monochloracid of the acetic series, or by heating the alkaline salt of such an acid with water or potassium hydrate:

(3.) By reducing the corresponding acid of the oxalic series by nascent hydrogen:

Carbonic acid— $\text{CO} \begin{array}{l} \text{OH} \\ \diagup \\ \text{OH} \end{array}$ —62.—Although this acid has not been isolated, it probably exists in aqueous solutions of  $\text{CO}_2$ , which have an acid reaction, while dry  $\text{CO}_2$  is neutral. Its salts, the carbonates, are well characterized.

Glycollic acid— $\begin{array}{c} \text{CH}_2\text{OH} \\ | \\ \text{COOH} \end{array}$ —76—is formed by the oxidation of gly-

col, by the action of nitrous acid on glycol, and by the action of potash on monochloracetic acid.

It forms deliquescent, acicular crystals; very soluble in water; soluble in alcohol and ether; has a strongly acid taste and reaction; fuses at  $78^\circ$  ( $172.4^\circ \text{F.}$ ); is decomposed at  $150^\circ$  ( $302^\circ \text{F.}$ ); at an

intermediate temperature it loses  $\text{H}_2\text{O}$ , forming glycolid, or glycollic anhydrid,  $\text{C}_2\text{H}_2\text{O}_2$ .

**Lactic acids**— $\text{C}_3\text{H}_5\text{O}_3$ —90.—There are probably three, certainly two, acids having this composition. Two of these would seem, from their products of decomposition, to be of similar constitution, while the molecular composition of the third is distinct. The two of similar constitution are sometimes designated as **ethylidene lactic acids**, because of their containing the group of atoms  $\text{CH}_3$ , while the third is designated as **ethyleno-lactic acid**, as it contains the group  $\text{CH}_2$ . Their constitution is expressed by the formulæ:

Obviously it is the ethylene acid which is the superior homologue of glycollic acid.

**Ethyleno-lactic Acid.**—Muscular tissue contains a mixture of this and optically active ethylidene lactic acid, which has been known as **sarcolactic acid**.

Ethyleno-lactic acid may be obtained from muscular tissue or from Liebig's extract of meat. It is optically inactive, as are also solutions of its salts; its zinc salt contains 2 Aq. and is very soluble in water and quite soluble in alcohol. When oxidized by chromic acid it yields malonic acid.

Of the two ethylidene lactic acids, that which is *optically active* is the one accompanying ethylene lactic acid, and predominating over it in amount, in dead muscle. It is to this acid that the name **paralactic acid** is most properly applied. It may be obtained from Liebig's meat extract.

Paralactic acid differs from its two isomeres in that its solutions are dextrogyrous, and the solutions of its salts are levogyrous. The specific rotary power of the acid is  $[\alpha]_D = +3^\circ.5$ ; that of the zinc salt  $[\alpha]_D = -7^\circ.6$ ; and of the calcium salt  $[\alpha]_D = -3^\circ.8$ . Its products of decomposition are the same as those of ordinary lactic acid.

**Ordinary Lactic Acid**—*Lactic acid of fermentation*—*Optically inactive ethylidene lactic acid*—**Acidum lacticum (U. S.)**—exists in nature, widely distributed in the vegetable kingdom, and as the product of a fermentation which is designated as the lactic, in milk, sour-kraut, fermented beet-juice, and rice, and in the liquid refuse of starch factories and tanneries.

Lactic acid is obtained as a product of the fermentation of certain sugars, milk-sugar and grape-sugar; as a result of the processes of nutrition of a minute vegetable, the lactic ferment, in

which the sugar is converted into its inferior polymere:  $C_6H_{12}O_6 = 2C_3H_6O_3$ . It is usually produced by allowing a mixture of cane-sugar, tartaric acid, water, rotten cheese, skim milk and chalk to ferment for 10 days at  $35^\circ$  ( $95^\circ$  F.). The calcium lactate produced is separated, purified and decomposed with an equivalent quantity of  $H_2SO_4$ .

It has also been obtained synthetically by oxidation of the propylglycol of Wurtz, which is a secondary glycol, a synthesis which indicates its constitution:

It is a colorless, syrupy liquid; sp. gr. 1.215 at  $20^\circ$  ( $68^\circ$  F.); does not solidify at  $-24^\circ$  ( $-11.2^\circ$  F.); soluble in water, alcohol, and ether; is not capable of distillation without decomposition; when heated to  $130^\circ$  ( $266^\circ$  F.) it loses water and is converted into dilactic acid,  $C_6H_{10}O_5$ , and, when heated to  $250^\circ$  ( $482^\circ$  F.), into lactid,  $C_3H_4O_2$ . It is a good solvent of tricalcic phosphate.

Oxidizing agents convert this acid into formic and acetic acids, without the formation of any malonic acid.

The three lactic acids occur in animal nature, either free or in combination. Free lactic acid of fermentation occurs in the contents of the small intestine, and, when vegetable food has been taken, in the stomach. It is not, however, the acid to which the *normal, unmixed* gastric juice owes its acidity. Its salts have been found to exist in the contents of the stomach and those of the intestines, chyle, bile, parenchymatous fluid of spleen, liver, thymus, thyroid, pancreas, lungs, and brain; urine. Pathologically in the blood in leucocythæmia, pyæmia, puerperal fever, and after excessive muscular effort; in the fluids of ovarian cysts and transudations. In the urine it is abundant in phosphorus-poisoning, in acute atrophy of the liver, and in rachitis and osteomalachia.

Muscular tissue, after death or continued contractions, contains the mixture of acids known as sarcolactic acid. Normal, quiescent muscle is neutral in reaction; but, when rigor mortis appears, or if the muscle be tetanized, its reaction becomes acid from the liberation of sarcolactic acid. Whether these acids are formed *de novo* during the contraction of the muscle, or whether they are produced by the decomposition of lactates existing in the quiescent muscle, is still undetermined; certain it is, however, that a given quantity of muscle has when separated from the circulation, a fixed maximum of acid-producing capacity, which is

greater in a muscle that has been tetanized during the interval between its removal and the establishment of rigor, than in one which has been at rest.

There exist no grounds upon which to base the supposition that, in rheumatic fever, lactic acid is present in the blood.

### OXIDS AND SULPHIDS OF CARBON.

As the saturated compound of carbon and oxygen is the anhydrid of carbonic acid, the first of the series of acids just considered, it and its congeners may be appropriately treated of in this place.

**Carbon monoxid—Carbonous oxid—Carbonic oxid—CO—28**—is formed: (1.) By burning C with a limited supply of air. (2.) By passing dry carbon dioxid over red-hot charcoal. (3.) By heating oxalic acid with  $\text{H}_2\text{SO}_4$ :  $\text{C}_2\text{O}_4\text{H}_2 = \text{H}_2\text{O} + \text{CO} + \text{CO}_2$ ; and passing the gas through sodic hydrate to separate  $\text{CO}_2$ . (4.) By heating potassium ferrocyanid with  $\text{H}_2\text{SO}_4$ .

It is a colorless, tasteless gas; sp. gr. 0.9678A; very sparingly soluble in  $\text{H}_2\text{O}$  and in alcohol.

It burns in air with a blue flame and formation of carbon dioxid; it forms explosive mixtures with air and oxygen; it is oxidized to carbon dioxid by cold chromic acid. It is a valuable reducing agent, and is used for the reduction of metallic oxids at a red heat. Ammoniacal solutions of the cuprous salts absorb it readily. Being non-saturated, it unites readily with O to form  $\text{CO}_2$ , and with Cl to form  $\text{COCl}_2$ , the latter a colorless, suffocating gas, known as phosgene, or carbonyl chlorid.

**Toxicology.**—Carbon monoxid is an exceedingly poisonous gas, and is the chief toxic constituent of the gases given off from blast-furnaces, from defective flues, and open coal or charcoal fires, and of illuminating gas. An atmosphere containing but a small proportion of this gas produces asphyxia and death, even if the quantity of oxygen present be equal to or even greater than that normally existing in the atmosphere; 0.5 per cent. of CO in air is sufficient to kill a small bird in a few moments, and one per cent. proves fatal to small mammals.

Poisoning by CO may occur in several ways. By inhalation of the gases discharged from blast-furnaces and from copper-furnaces, the former containing 25 to 32 per cent., and the latter 13 to 19 per cent. of CO. By the fumes given off from charcoal burned in a confined space, which consist of a mixture of the two oxids of carbon, the dioxid predominating largely, especially when the combustion is most active. The following is the composition of an atmosphere produced by burning charcoal in a confined space, and which proved rapidly fatal to a dog: oxygen, 19.19; nitrogen, 76.62; carbon dioxid, 4.61; carbon monoxid, 0.54; marsh-gas, 0.04.

Obviously the deleterious effects of charcoal-fumes are more rapidly fatal in proportion as the combustion is imperfect and the room small and ill-ventilated.

A fruitful source of CO poisoning, sometimes fatal, but more frequently producing languor, headache, and debility, is to be found in the stoves, furnaces, etc., used in heating our dwellings and other buildings, especially when the fuel is anthracite coal. This fuel produces in its combustion, when the air-supply is not abundant, considerable quantities of CO, to which a further addition may be made by a reduction of the dioxid, also formed, in passing over red-hot iron.

Of late years cases of fatal poisoning by illuminating gas are of very frequent occurrence, caused either by accidental inhalation, by inexperienced persons blowing out the gas, or by suicides. The most actively poisonous ingredient of illuminating gas is CO, which exists in the ordinary coal-gas in the proportion of 4 to 7.5 per cent., and in water-gas, made by decomposing superheated steam by passage over red-hot coke, and subsequent charging with vapor of hydrocarbons, in the large proportion of 30-35 per cent.

The method in which CO produces its fatal effects is by forming with the blood-coloring matter a compound which is more stable than oxyhæmoglobin, and thus causing asphyxia by destroying the power of the blood-corpuscles of carrying O from the air to the tissues. This compound of CO and hæmoglobin is quite stable, and hence the symptoms of this form of poisoning are very persistent, lasting until the place of the coloring-matter thus rendered useless is supplied by new formation. The prognosis is very unfavorable when the amount of the gas inhaled has been at all considerable. The treatment usually followed, *i.e.*, artificial respiration, and inhalation of O, failing to restore the altered coloring-matter. There would seem to be no form of poisoning in which transfusion of blood is more directly indicated than in that by CO.

**Detection after death.**—The blood of those asphyxiated by CO is persistently bright red in color. When suitably diluted and examined with the spectroscope, it presents an absorption spectrum (Fig. 36) of two bands similar to that of oxyhæmoglobin (Fig. 16, No. 11), but in which the two bands are more equal and somewhat nearer the violet end of the spectrum. Owing to the greater stability of the CO compound, its spectrum may be readily distinguished from that of the O compound by the addition of a reducing agent (an ammoniacal solution of ferrous tartrate), which changes the spectrum of oxyhæmoglobin to the single-band spectrum of hæmoglobin (Fig. 16, No. 12), while that of the CO compound remains unaltered, or only fades partially.

If a solution of caustic soda of sp. gr. 1.3 be added to normal blood a black, slimy mass is formed, which, when spread upon a white plate, has a greenish-brown color. The same reagent added to blood altered by CO forms a firmly clotted mass, which in thin layers upon a white surface is bright red in color.

A piece of gun-cotton upon which platinum-black has been dusted fires in air containing 2.5 in 1,000 of CO.

For the method of determining CO in gaseous mixtures, see p. 324.

**Carbon dioxid—Carbonic anhydrid—Carbonic acid gas—CO<sub>2</sub>—44**—is obtained: (1.) By burning C in air or O. (2.) By decomposing a carbonate (marble= $\text{CaCO}_3$ ) by a mineral acid (HCl diluted with an equal volume of H<sub>2</sub>O).

At ordinary temperatures and pressures it is a colorless, suffocating gas; has an acidulous taste; sp. gr. 1.529A; soluble in an equal volume of H<sub>2</sub>O at the ordinary pressure; much more soluble as the pressure increases. **Soda water** is a solution of carbonic

FIG. 36.

acid in H<sub>2</sub>O under increased pressure. When compressed to the extent of 38 atmospheres at 0° (32° F.); 50 atm. at 15° (59° F.); or 73 atm. at 30° (86° F.) it forms a transparent, mobile liquid, by whose evaporation, when the pressure is relieved, sufficient cold is produced to solidify a portion into a snow-like mass, which, by spontaneous evaporation in air, produces a temperature of -90° (-130° F.).

Carbon dioxid neither burns nor does it support combustion. When heated to 1,300° (2,370° F.), it is decomposed into CO and O. A similar decomposition is brought about by the passage through it of electric sparks. When heated with H it yields CO and H<sub>2</sub>O. When K, Na or Mg is heated in an atmosphere of CO<sub>2</sub>, the gas is decomposed with formation of a carbonate and separation of carbon. When caused to pass through solutions of the hydrates of Na, K, Ca, or Ba, it is absorbed, with formation of the carbonates of those elements, which, in the case of the last two, are deposited as white precipitates. Solution of potash is frequently used in analysis to absorb CO<sub>2</sub>, and lime and baryta water as tests for its presence. The hydrates mentioned also absorb CO<sub>2</sub> from moist air.

**Atmospheric Carbon Dioxid.**—Carbon dioxid is a constant constituent of atmospheric air in small and varying quantities; the mean amount in free country air being about 4 in 10,000. The variation in amount under different conditions is shown in the following table:

AMOUNT OF CARBON DIOXID IN AIR.

Collected at	Parts in 10,000.	Determined by
Paris . . . . .	3.190	Boussingault and Lewy.
Andilly (twenty miles from Paris. . . . .	2.989	Boussingault and Lewy.

Grotto del Cane . . . . .	7,360.0	F. Leblanc.

It will be observed that on land the amount is greater by night than by day, while the reverse is the case at sea; on land the green parts of plants absorb  $\text{CO}_2$  during the hours of sunlight, but not during those of darkness. The increase in the amount in air over large bodies of water during the daytime is due to the less solubility of  $\text{CO}_2$  in the surface-water when heated by the sun's rays. The absence of vegetation accounts for the large quantity of  $\text{CO}_2$  in the air of the polar regions, and the same cause, aided by an increased production, for its excess in the air of cities over that of the country.

The sources of atmospheric  $\text{CO}_2$  are:

(1.) *The respiration of animals.*—The air expired from the lungs of animals contains a quantity of  $\text{CO}_2$ , varying with the age, sex, food, and muscular development and activity, while, at the same time, a much smaller quantity is discharged by the skin and in solution in the urine.

The expired air under ordinary conditions contains about 4.5

per cent. by volume of  $\text{CO}_2$ , the proportion being greater the slower the respiration.

(2.) *Combustion.*—The greater part of the atmospheric  $\text{CO}_2$  is a product of the oxidation of C in some form as a source of light and heat. In the following table are given the amounts of  $\text{CO}_2$  produced, and of air consumed, by different kinds of fuel and illuminating materials. In equal times, an ordinary gas-burner

produces nearly six times as much  $\text{CO}_2$ , and consumes nearly ten times as much air as a man. The amount of air consumed by fuel is, for practical purposes, greater than that given in the

table, as the oxidation is never complete, the air in the chimney frequently containing ten per cent. of oxygen by volume.

(3.) *Fermentation*.—Most fermentations, including putrefactive changes, are attended by the liberation of  $\text{CO}_2$ . Thus, alcoholic fermentation takes place according to the equation:

and consequently discharges into the air 88 parts by weight of  $\text{CO}_2$  for every 92 parts of alcohol formed, or 384 litres of gas for every litre of absolute alcohol obtained.

(4.) *Tellural sources*.—Volcanoes in activity discharge enormous quantities of  $\text{CO}_2$ , and, in volcanic countries, the same gas is thrown out abundantly through fissures in the earth. All waters, sweet and mineral, hold this gas in solution, and those which have become charged with it under pressure in the earth's crust, upon being relieved of the pressure when they reach the surface, discharge the excess into the air.

(5.) *Manufacturing processes*.—Large quantities of  $\text{CO}_2$  are added to the air in the vicinity of lime- and brick-kilns, cement-works, etc.

(6.) *In mines*, after explosions of "fire-damp." These explosions are caused by the sudden union of the C and H of  $\text{CH}_4$ , with the O of the air, and are consequently attended by the formation of large volumes of  $\text{CO}_2$ , known to miners as *after-damp*.

**Constancy of the amount of atmospheric carbon dioxid.**—It has been roughly estimated by Poggendorff that 2,500,000,000,000 cubic metres of  $\text{CO}_2$  are annually discharged into our atmosphere, and that this quantity represents one-eighty-sixth of the total amount at present existing therein. This being the case, with the present production, the percentage of atmospheric  $\text{CO}_2$  would be doubled in eighty-six years. No such increase has, however, been observed, and the average percentage found by Angus Smith, in 1872, is about the same as that observed by Boussingault in 1840, *i.e.*, four parts in ten thousand. The  $\text{CO}_2$  discharged into the air is, therefore, removed from it about as fast as it is produced. This removal is effected in two ways: (1) by the formation of deposits of earthy carbonates by animal organisms, corals, mollusks, etc.; (2) principally by the process of nutrition of vegetables, which absorb  $\text{CO}_2$  both by their roots and leaves, and in the latter, under the influence of the sun's rays, decompose it, retaining the C, which passes into more complex molecules; and discharging a volume of O about equal to that of the  $\text{CO}_2$  absorbed.

**Air contaminated with excess of carbon dioxid, and its effects upon the organism.**—When, from any of the above sources, the air of a given locality has received sufficient  $\text{CO}_2$  to raise the pro-

portion above 7 in 10,000 by volume, it is to be considered as contaminated; the seriousness of the contamination depending not only upon the amount of the increase, but also upon the source of the  $\text{CO}_2$ . If the gas be derived from fermentation, or from tellural or manufacturing sources, it is simply added to the otherwise unaltered air, and the absolute amount of oxygen present remains the same. When, however, it is produced in a confined space by the processes of combustion and respiration, the composition of the air is much more seriously modified, as not only is there addition of a deleterious gas, but a simultaneous removal of an equal volume of  $\text{O}$ ; hence the importance of providing, by suitable ventilation, for the supply of new air from without to habitations and other places where human beings are collected within doors, especially where the illumination is artificial.

Although an adult man deoxidizes a little over 100 litres of air in an hour, a calculation of the quantity which he would require in a given time cannot be based exclusively upon that quantity, as the deoxidation cannot be carried to completeness; indeed, when the proportion of  $\text{CO}_2$  in air exceeds five per cent., it becomes incapable of supporting life, while a much smaller quantity, one per cent., is provocative of severe discomfort, to say the least.

In calculating the quantity of air which should be supplied to a given enclosed space, most authors have agreed to adopt as a basis that the percentage of  $\text{CO}_2$  should not be allowed to exceed 0.6 volume per 1,000; of which 0.4 is normally present in air, and 0.2 the product of respiration or combustion. Taking the amount of  $\text{CO}_2$  eliminated by an adult at 19 litres (= 0.7 cubic foot) per hour, a man will have brought the air of an air-tight space of 100 cubic metres (= 3,500 cubic feet) up to the permissible maximum of impurity in an hour.

Practically, owing to the imperfect closing of doors and windows, and to ventilation by chimneys, inhabited spaces are never hermetically closed, and a less quantity of air-supply than would be required in an air-tight space will suffice.

A sleeping-room occupied by a single person should have a cubic space of 30 to 50 cubic metres (= 1,050 to 1,800 cubic feet), conditions which are fulfilled in rooms measuring  $10 \times 13 \times 8$  feet, and  $13 \times 15.6 \times 9$  feet.

In calculating the space of dormitories to be occupied by several healthy people, the smallest air-space that should, under any circumstances, be allowed, is 12 cubic metres (= 420 cubic feet) for each person. To determine the number of individuals that may sleep in a room, multiply its length, width, and height together, and divide the product by 420 if the measurement be in feet, or by 12 if it be in metres. Thus, a dormitory 40 feet long, 20 feet

wide, and 10 feet high, is fitted for the accommodation of 19 persons at most; for  $40 \times 20 \times 10 = 8,000$ , and  $\frac{8,000}{420} = 19.05$ .

As a rule, in places where many persons are congregated, it is necessary to resort to some scheme of ventilation by which a sufficient supply of fresh air shall be introduced and the vitiated air removed, the quantity to be supplied varying according to circumstances. Experiment has shown that, in order to keep the air pure to the senses, the quantity of air which must be supplied per head and per hour in temperate climates is as shown in the table:

Situation.	Cubic metres.	Cubic feet.	Situation.	Cubic metres.	Cubic feet.
Barracks (day-time) . . . . .	35	1,236	Hospital wards (surgical) . . . . .	170	6,004
Barracks (night-time) . . . . .	70	2,472	Contagious and lying-in . . . . .	170	6,004
Workshops (mechanical) . . . . .	70	2,472	Mines, metaliferous . . . . .	150	5,295
School-rooms . . . . .	35	1,236	Mines, coal . . . . .	170	6,004
Hospital wards . . . . .	85	3,002			

The amounts given are the smallest permissible, and should be exceeded wherever practicable.

*Lights.*—Each cubic foot of illuminating-gas consumes in its combustion a quantity of O equal to that contained in 7.14 cubic feet of air, and produces 0.8 cubic feet of  $\text{CO}_2$ , besides a large quantity of watery vapor, and less amounts of  $\text{H}_2\text{SO}_4$ ,  $\text{SO}_2$ , and sometimes CO; and an ordinary gas-burner consumes about three feet per hour. It is obvious, therefore, that a much larger quantity of pure air must be furnished to maintain the atmosphere of an apartment at the standard of 0.6 per 1,000 of  $\text{CO}_2$ , when the vitiation is produced by the combustion of gas, than when it is the result of the respiration of a human being, and that to such an extent that a single three-foot burner requires a supply of air which would be sufficient for six human beings.

In theatres the contamination of the air by the burning of gas should be entirely eliminated by placing the burners either under the dome ventilator, or in boxes which open to the air of the house only below the level of the burner, and which are in communication with a ventilating-shaft.

When artificial illumination is obtained from lamps or candles, or from gas in small quantity and for a short time, the contamination of the air is sufficiently compensated by the ventilation through imperfect closing of the windows. A room without a window should never be used for human habitation.

One important advantage of the electric light is that it consumes no O and produces no  $\text{CO}_2$ .

Although, by the combustion of fuel, O is consumed and  $\text{CO}_2$  produced, heating arrangements only become a source of vitiation of air when they are improperly constructed. Indeed, in the ma-

majority of cases, if properly arranged, they are the means of ventilation, either by aspirating the vitiated air of the apartment, or by the introduction of air from without.

**Action on the economy.**—An animal introduced into an atmosphere of pure  $\text{CO}_2$  dies almost instantly, and without entrance of the gas into the lungs, death resulting from spasm of the glottis, and consequent apnœa.

When diluted with air, the action of  $\text{CO}_2$  varies according to its proportion, and according to the proportion of O present.

When the proportion of O is not diminished, the poisonous action of  $\text{CO}_2$  is not as manifest, in equal quantities, as when the air is poorer in oxygen. An animal will die rapidly in an atmosphere composed of 21 per cent. O, 59 per cent. N, and 20 per cent.  $\text{CO}_2$  by volume; but will live for several hours in an atmosphere whose composition is 40 per cent. O, 37 per cent. N, 23 per cent.  $\text{CO}_2$ . If  $\text{CO}_2$  be added to normal air, of course the relative quantity of O is slightly diminished, while its absolute quantity remains the same. This is the condition of affairs existing in nature when the gas is discharged into the air; under these circumstances an addition of 10–15 per cent. of  $\text{CO}_2$  renders an air rapidly poisonous, and one of 5–8 per cent. will cause the death of small animals more slowly. Even a less proportion than this may become fatal to an individual not habituated.

In the higher states of dilution,  $\text{CO}_2$  produces immediate loss of muscular power, and death without a struggle; when more dilute, a sense of irritation of the larynx, drowsiness, pain in the head, giddiness, gradual loss of muscular power, and death in coma.

If the  $\text{CO}_2$  present in air be produced by respiration, or combustion, the proportion of O is at the same time diminished, and much smaller absolute and relative amounts of the poisonous gas will produce the effects mentioned above. Thus, an atmosphere containing in volumes 19.75 per cent. O, 74.25 per cent. N, 6 per cent.  $\text{CO}_2$ , is much more rapidly fatal than one composed of 21 per cent. O, 59 per cent. N, 20 per cent.  $\text{CO}_2$ . With a corresponding reduction of O, 5 per cent. of  $\text{CO}_2$  renders an air sufficiently poisonous to destroy life; 2 per cent. produces severe suffering; 1 per cent. causes great discomfort, while 0.1 per cent., or even less, is recognized by a sense of closeness.

The treatment in all cases of poisoning by  $\text{CO}_2$  consists in the inhalation of pure air (to which an excess of O may be added), aided, if necessary, by artificial respiration, the cold douche, galvanism, and friction.

**Detection of carbon dioxid and analysis of confined air.**—Carbon dioxid, or air containing it, causes a white precipitate when caused to bubble through lime or baryta water. Normal air con-

tains enough of the gas to form a scum upon the surface of these solutions when exposed to it.

It was, at one time supposed that air in which a candle continued to burn was also capable of maintaining respiration. This is, however, by no means necessarily true. A candle introduced into an atmosphere in which the normal proportion of O is contained, burns readily in the presence of 8 per cent. of  $\text{CO}_2$ ; is perceptibly dulled by 10 per cent.; is usually extinguished with 13 per cent.; always extinguished with 16 per cent. Its extinction is caused by a less proportion of  $\text{CO}_2$ , 4 per cent., if the quantity of O be at the same time diminished. Moreover, a contaminated atmosphere may not contain enough  $\text{CO}_2$  to extinguish, or per-

FIG. 37.

ceptibly dim the flame of a candle, and at the same time contain enough of the monoxid to render it fatally poisonous if inhaled.

The presence of  $\text{CO}_2$  in a gaseous mixture is determined by its absorption by a solution of potash; its quantity either by measuring the diminution in bulk of the gas, or by noting the increase in weight of an alkaline solution.

To determine the proportions of the various gases present in air the apparatus shown in Fig. 37 is used. A is an aspirator of known capacity, filled with water at the beginning of the operation. It connects by a flexible tube from its upper part with an absorbing apparatus consisting of *a*, a U-shaped tube containing fragments of pumice-stone, moistened with  $\text{H}_2\text{SO}_4$ ; by the increase in weight of this tube the weight of watery vapor in the volume of air drawn through by the aspirator is determined; *b*, a Liebig's bulb filled with a solution of potash; *c*, a U-tube filled with fragments of pumice moistened with  $\text{H}_2\text{SO}_4$ ; *b* and *c* are weighed together and their increase in weight is the weight of

$\text{CO}_2$  in the volume of air operated on. Every gram of increase in weight represents 0.50607 litre, or 31.60356 cubic inches;  $d$  is a tube of difficultly fusible glass, filled with black oxid of copper and heated to redness;  $e$  is a U tube filled with pumice moistened with  $\text{H}_2\text{SO}_4$ ; its increase in weight represents  $\text{H}_2\text{O}$  obtained from decomposition of  $\text{CH}_4$ . Every gram of increase in weight of  $e$  represents 0.444 gram, or 0.621 litre, or 38.781 cubic inches of marsh-gas;  $f$  and  $g$  are similar to  $b$  and  $c$ , and their increase in weight represents  $\text{CO}_2$  formed by oxidation of  $\text{CO}$  and  $\text{CH}_4$  in  $d$ . From this the amount of  $\text{CO}$  is thus calculated: First, 2.75 grams are deducted from the increase of weight of  $f$  and  $g$  for each gram of  $\text{CH}_4$  formed by  $e$ ; of the remainder, every gram represents 0.6364 gram, or 0.5085 litre, or 31.755 cubic inches of  $\text{CO}$ . The air is drawn through the apparatus by opening the stopcock of  $A$  to such an extent that about 30 bubbles a minute pass through  $b$ .

**Carbon disulphid—Bisulphid of carbon—Carbonei bisulphidum (U. S.)— $\text{CS}_2$ —76**—is formed by passing vapor of S over C heated to redness, and is partly purified by rectification.

It is a colorless liquid; when pure it has a peculiar, but not disagreeable odor, the nauseating odor of the commercial product being due to the presence of another sulphurated body; boils at 47 ( $116.6^\circ \text{F.}$ ); sp. gr. 1.293; very volatile; its rapid evaporation in vacuo produces a cold of  $-60$  ( $-76^\circ \text{F.}$ ); it does not mix with  $\text{H}_2\text{O}$ ; it refracts light strongly.

It is highly inflammable, and burns with a bluish flame, giving off  $\text{CO}_2$  and  $\text{SO}_2$ ; its vapor forms highly explosive mixtures with air, which detonate on contact with a glass rod heated to 250 ( $482^\circ \text{F.}$ ). Its vapor forms a mixture with nitrogen dioxid, which, when ignited, burns with a brilliant flame, rich in actinic rays.

There also exists a substance intermediate in composition between  $\text{CO}_2$  and  $\text{CS}_2$ , known as carbon oxysulphid,  $\text{CSO}$ , which is an inflammable, colorless gas, obtained by decomposing potassium sulphocyanate with dilute  $\text{H}_2\text{SO}_4$ .

**Toxicology.**—Cases of acute poisoning by  $\text{CS}_2$  have hitherto only been observed in animals; its action is very similar to that of chloroform.

Workmen engaged in the manufacture of  $\text{CS}_2$  and in the vulcanization of rubber, as well as others exposed to the vapor of the disulphid, are subject to a form of chronic poisoning which may be divided into two stages. The first, or stage of excitation, is marked by headache, vertigo, a disagreeable taste, cramps in the legs; the patient talks, laughs, sings, and weeps immoderately, and sometimes becomes violently delirious. In the second stage the patient becomes sad and sleepy, sensibility diminishes, sometimes to the extent of complete anesthesia, especially of the lower extremities, the headache becomes more intense, the appetite is greatly impaired, and there is general weakness of the limbs, which terminates in paralysis.

The only remedy which has been suggested is thorough ventilation of the workshops, and abandonment of the trade at the first appearance of the symptoms.

### DIATOMIC AND DIBASIC ACIDS.

#### SERIES $\text{CH}_{2n-2}\text{O}_4$ .

Oxalic acid .....	$\text{C}_2\text{O}_4\text{H}_2$	Pimelic acid .....	$\text{C}_7\text{O}_4\text{H}_{12}$
Malonic acid.....	$\text{C}_3\text{O}_4\text{H}_4$	Suberic acid.....	$\text{C}_8\text{O}_4\text{H}_{14}$
Succinic acid.....	$\text{C}_4\text{O}_4\text{H}_6$	Azelaic acid.....	$\text{C}_9\text{O}_4\text{H}_{16}$
Deoxyglutanic acid....	$\text{C}_5\text{O}_4\text{H}_8$	Sebacic acid.....	$\text{C}_{10}\text{O}_4\text{H}_{18}$
Adipic acid.....	$\text{C}_6\text{O}_4\text{H}_{10}$	Roccellic acid....	$\text{C}_{17}\text{O}_4\text{H}_{32}$

They are derived from the primary glycols by complete oxidation; they are diatomic and dibasic, and contain two groups,  $\text{CO}$ ,  $\text{OH}$ . They form two series of salts with the univalent metals, and two series of ethers, one of which contains neutral, and the other acid ethers. They may be obtained from the corresponding glycols, or from acids of the preceding series, by oxidation.

$\text{COOH}$   
Oxalic acid—|—90— $\text{C}_2\text{O}_4\text{H}_2$ , 2Aq—126—does not occur free  
 $\text{COOH}$

in nature, but in the oxalates of K, Na, Ca, Mg, and Fe in the juices of many plants: sorrel, rhubarb, cinchona, oak, etc.: as a native ferrous oxalate; and in small quantity in human urine. It is prepared artificially by oxidizing sugar or starch by  $\text{HNO}_3$ , or by the action of an alkaline hydrate in fusion upon sawdust. The soluble alkaline oxalate obtained by the latter method is converted into the insoluble Ca or Pb salt, which is washed and decomposed by an equivalent quantity of  $\text{H}_2\text{SO}_4$  or  $\text{H}_2\text{S}$ ; and the liberated acid purified by recrystallization.

Oxalic acid is also formed by the oxidation of many organic substances—alcohol, glycol, sugar, etc.: by the action of potassa in fusion upon the alkaline formates; and by the action of K or Na upon  $\text{CO}_2$ .

It crystallizes in transparent prisms, containing 2Aq, which effloresce on exposure to air, and lose their Aq slowly but completely at 100 (212 F.), or in a dry vacuum. It fuses at 98 (208.4 F.) in its Aq; at 110–132 (230–269.6 F.) it sublimes in the anhydrous form, while a portion is decomposed; above 160 (320 F.) the decomposition is more extensive:  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{CO}$ , and formic acid are produced, while a portion of the acid is sublimed unchanged. It dissolves in 15.5 parts of water at 10 (50 F.); the presence of  $\text{HNO}_3$  increases its solubility. It is quite soluble in alcohol. It has a sharp taste and an acid reaction in solution.

Oxalic acid is readily oxidized; in watery solution it is converted into  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , slowly by simple exposure to air, more

rapidly in the presence of platinum-black or of the salts of platinum and gold; under the influence of sunlight; or when heated with  $\text{HNO}_3$ , manganese dioxid, chromic acid, Br, Cl, or hypochlorous acid. Its oxidation, when it is triturated dry with lead dioxid, is sufficiently active to heat the mass to redness.  $\text{H}_2\text{SO}_4$ ,  $\text{H}_3\text{PO}_4$ , and other dehydrating agents decompose it into  $\text{H}_2\text{O}$ ,  $\text{CO}$ , and  $\text{CO}_2$ .

**Analytical Characters.**—(1.) In neutral or alkaline solution a white ppt. with a solution of a Ca salt. (2.) Silver nitrate, a white ppt., soluble in  $\text{HNO}_3$  and in  $\text{NH}_4\text{HO}$ . The ppt. does not darken when the fluid is boiled, but, when dried and heated on platinum foil, it explodes. (3.) Lead acetate, in solutions not too dilute, a white ppt., soluble in  $\text{HNO}_3$ , insoluble in acetic acid.

**Toxicology.**—Although certain oxalates are constant constituents of vegetable food and of the human body, the acid itself, as well as hydropotassic oxalate, is a violent poison when taken internally, acting both locally as a corrosive upon the tissues with which it comes in contact, and as a true poison, the predominance of either action depending upon the concentration of the solution. Dilute solutions may produce death without pain or vomiting, and after symptoms resembling those of narcotic poisoning. Death has followed a dose of  $\frac{1}{2}$  i. of the solid acid, and recovery a dose of  $\frac{3}{4}$  i. in solution. When death occurs, it may be almost instantaneously, usually within half an hour; sometimes after weeks or months, from secondary causes.

The treatment, which must be as expeditious as possible, consists in the administration, *first*, of lime or magnesia, or a soluble salt of Ca or Mg suspended or dissolved in a *small* quantity of  $\text{H}_2\text{O}$  or mucilaginous fluid; afterward, if vomiting have not occurred spontaneously, and if the symptoms of corrosion have not been severe, an emetic may be given. In the treatment of this form of poisoning several points of negative caution are to be observed. As in all cases in which a corrosive has been taken internally, the use of the stomach-pump is to be avoided. The alkaline carbonates are of no value in cases of oxalic-acid poisoning, as the oxalates which they form are soluble, and almost as poisonous as the acid itself. The ingestion of water, or the administration of warm water as an emetic, is contraindicated when the poison has been taken in the solid form (or where doubt exists as to what form it was taken in), as they dissolve, and thus favor the absorption of the poison.

**Analysis.**—In fatal cases of poisoning by oxalic acid the contents of the stomach are sometimes strongly acid in reaction; more usually, owing to the administration of antidotes, neutral, or even alkaline. In a systematic analysis the poison is to be sought for in the residue of the portion examined for prussic acid

and phosphorus; or, if the examination for those substances be omitted, in the residue or final alkaline fluid of the process for alkaloids. If oxalic acid alone is to be sought for, the contents of the stomach, or other substances *if acid*, are extracted with water, the liquid filtered, the filtrate evaporated, the residue extracted with alcohol, the alcoholic fluid evaporated, the residue redissolved in water (solution No. 1). The portion undissolved by alcohol is extracted with alcohol acidulated with hydrochloric acid, the solution evaporated after filtration, the residue dissolved in water (solution No. 2). Solution No. 1 contains any oxalic acid which may have existed free in the substances examined; No. 2 that which existed in the form of soluble oxalates. If lime or magnesia have been administered as an antidote, the substances must be boiled for an hour or two with potassium carbonate (not the hydrate), filtered, and the filtrate treated as above. In the solutions so obtained, oxalic acid is characterized by the tests given above. The urine is also to be examined microscopically for crystals of calcium oxalate. The stomach may contain small quantities of oxalates as normal constituents of certain foods.

**Malonic acid**— $\text{CH}_2 \begin{smallmatrix} \diagup \text{COOH} \\ \diagdown \text{COOH} \end{smallmatrix}$ —is a product of the oxidation of malic acid, or of normal propyl glycol. It forms large prismatic crystals, soluble in water, alcohol and ether; fusible at  $132^\circ$  ( $269.6^\circ \text{ F.}$ ), and decomposed at about  $150^\circ$  ( $302^\circ \text{ F.}$ ) into acetic acid and carbon dioxide.

**Succinic acids**—Two isomeres are known.

**Succinic acid**— $\begin{smallmatrix} \text{CH}_3\text{—COOH} \\ | \\ \text{CH}_2\text{—COOH} \end{smallmatrix}$ —118—exists in amber, coal, fossil

wood, and in small quantity in animal and vegetable tissues. Its presence has been detected in the normal urine after the use of fruits and of asparagus, in the parenchymatous fluids of the spleen, thyroid, and thymus, and in the fluids of hydrocele and of hydatid cysts. It is also formed in small quantity during alcoholic fermentation; as a product of oxidation of many fats and fatty acids; and by synthesis from ethylene cyanid.

It may be obtained by dry distillation of amber, or, preferably, by the fermentation of malic acid.

It crystallizes in large prisms or hexagonal plates, which are colorless, odorless, permanent in air, acid in taste, soluble in water, sparingly so in ether and in cold alcohol. It fuses at  $180^\circ$  ( $356^\circ \text{ F.}$ ), and distils with partial decomposition at  $235^\circ$  ( $455^\circ \text{ F.}$ ). It withstands the action of oxidizing agents; reducing agents convert it into the corresponding acid of the fatty series, butyric acid; with Br it forms products of substitution;  $\text{H}_2\text{SO}_4$  is without action upon it; phosphoric anhydrid removes  $\text{H}_2\text{O}$  and converts it into **succinic anhydrid**,  $\text{C}_4\text{H}_4\text{O}_3$ .

Isosuccinic acid— $\text{CH}_3\text{—CH} \begin{smallmatrix} \text{COOH} \\ \text{COOH} \end{smallmatrix}$ —is formed by the action of hydrating agents upon cyanopropionic acid. It forms prismatic crystals, fusible at  $130^\circ$  ( $266^\circ \text{ F.}$ ), and is decomposed at higher temperatures into propionic acid and carbon dioxide.

### UNSATURATED ACIDS $\text{C}_n\text{H}_{2n-4}\text{O}_4$ .

These acids contain two atoms of H less than the corresponding acids of the oxalic series, like which, they are dibasic. In the higher terms there are many instances of isomerism, as shown in the formulæ of the derivatives of aconitic acid given below.

They are obtainable by the action of KI upon the dibrominated derivatives of the acids of the oxalic series.

Fumaric and Maleic Acids— $\text{C}_4\text{H}_4\text{O}_4$ —are produced together by the dry distillation of malic acid, by loss of the elements of a molecule of water. The difference in their molecular structure is shown by the formulæ :

Fumaric acid.

Maleic acid.

Fumaric acid exists in many plants, is a solid, crystalline body, sparingly soluble in cold, readily soluble in hot water. Nascent H converts it into succinic acid.

Mesaconic, Citraconic, Itaconic and Paraconic Acids— $\text{C}_5\text{H}_6\text{O}_4$ —may be considered as being the homologues, the first two of fumaric acid, the last two of maleic acid :

Mesaconic acid.

Citraconic acid.

Itaconic acid.

Paraconic acid.

Citraconic and itaconic acids are produced by the action of heat upon citric acid. Mesaconic and paraconic by the action of heat upon citrachloropyrotartaric and itachloropyrotartaric acids respectively.

## COMPOUND ETHERS OF THE ACIDS OF THE SERIES

The members of both of these series contain two atoms of H replaceable by alcoholic radicals. In those of the series  $C_nH_{2n}O_3$  (with the exception of carbonic acid), being monobasic, although diatomic, it is not immaterial which H is so replaced. If it be that of the group  $CH_2OH$ , the resulting compound is a monobasic acid, in which the H of the group  $COOH$  may be replaced by another alcoholic radical to form a neutral ether of the new acid. If, on the other hand, the H of the group  $COOH$  be first replaced, a neutral compound ether is formed. In the members of the series  $C_nH_{2n-2}O_4$ , which are dibasic, the substitution of an alcoholic radical for the H of either group  $COOH$  produces a monobasic acid, in which the H of the other  $COOH$  may be replaced by another radical to form a neutral ether. The following formulæ indicate the differences in the nature of these compounds :

## ALDEHYDES AND ANHYDRIDS OF THE SERIES

In treating of the monoatomic compounds, it was stated that substances existed corresponding to the fatty acids, known as aldehydes and anhydrids, the former differing from the acids in that they contained the group  $CHO$  instead of  $COOH$ ; the latter being the oxids of the acid radicals. Similar compounds exist corresponding to the acids of these two series.

The aldehydes corresponding to the series  $C_nH_{2n}O_3$  contain the group  $CHO$  in place of the group  $COOH$ , and as they also contain the group  $CH_2OH$ , they are possessed of the double function of primary alcohol and aldehyde. Those of the series  $C_nH_{2n-2}O_4$  form two series; in one of which only one of the groups  $COOH$  is deoxidized to  $CHO$ ; in the other, both. Those of the first series, still containing a group  $COOH$ , are monobasic acids as well as aldehydes :

While the anhydrids of the fatty series may be considered as derived from the acids by the subtraction of  $\text{H}_2\text{O}$  from two molecules of the acid ; those of both the series of acids under consideration are derived from a single molecule of the acid by the subtraction of  $\text{H}_2\text{O}$  :

## AMINS OF THE GLYCOLS.

### ETHYLENIC COMPOUND AMMONIAS—DIAMINS.

These substances are derived from a double molecule of  $\text{NH}_3$ , or of ammonium hydrate, by the substitution of the diatomic radicals of the glycols (hydrocarbons of the series  $\text{C}_n\text{H}_{2n}$ ) for an equivalent number of H atoms. They are distinguished from the corresponding compounds of the radicals of the monoatomic alcohols, the *monamins*, by the designation of *diamins*.

When it is considered that in the formation of these substances double H atoms can be replaced by diatomic radicals to form primary, secondary, and tertiary amins :

that others exist in which two univalent radicals replace a bivalent radical ; others, again, in which H atoms have been replaced by groups OH ; and finally, that similar compounds of P, As and Sb exist, it is not astonishing that the study of the vast number of substances, the possibility of whose existence is thus indicated, is still in its infancy.

Some recently discovered alkaloids, produced during putrefaction (see Ptomaines), are diamins ; and there is strong probability that further investigation will show some of the vegetable alkaloids, whose constitution is as yet unknown, to belong in this class.

Among the diamins are included the **amidins**, having the constitution  $R-C \begin{smallmatrix} \diagup NH \\ \diagdown NH_2 \end{smallmatrix}$ , in which R is a hydrocarbon radical; and these, on oxidation, yield a class of substances known as **amidoxims**, having the constitution  $R-C \begin{smallmatrix} \diagup NOH \\ \diagdown NH_2 \end{smallmatrix}$ .

### AMIDS OF THE ACIDS OF THE SERIES

This class of substances, formed by the substitution of radicals of the acids for H atoms in  $NH_3$  molecules, contains some substances of the greatest medical interest. The radicals of the acids of the series  $C_nH_{2n}O_3$ , except carbonic acid, being univalent, form amids similar in constitution to those of the acids of the series  $C_nH_{2n}O_2$  (p. 278).

In the case of the dibasic acids three series of amids are known to exist. Thus we have, corresponding to oxalic acid:

In the first of these, two H atoms of a single  $NH_3$  molecule are replaced by the bivalent radical of the acid; these are distinguished as **imids**. Those of the second series are normally formed **diamids**. In the third series, the univalent remainder, left by the removal of OH from the acid, replaces an atom of H in one molecule of  $NH_3$ , and the resulting compound, still containing a group COOH, has the functions of a monobasic acid.

**Carbimid—CONH—43**—is probably identical with cyanic acid (q.v.).

**Carbamid—Urea—** $\left. \begin{array}{c} (CO)'' \\ H_2 \\ H_2 \end{array} \right\} N_2-60$ .—Urea does not occur in the vegetable world. It exists principally in the urine of the mammalia; also in smaller quantity in the excrements of birds, fishes, and some reptiles; in the mammalian blood, chyle, lymph, liver, spleen, lungs, brain, vitreous and aqueous humors, saliva, perspiration, bile, milk, amniotic and allantoic fluids, muscular tissue, and in serous fluids (see below).

It is formed—(1.) As a product of the decomposition of uric acid, usually by oxidation:

(2.) By the oxidation of oxamid.

(3.) By the action of caustic potassa upon creatin :

4.) By the limited oxidation of albuminoid substances, by potassium permanganate, and during the processes of nutrition.

(5.) By the action of carbon oxychlorid on dry ammonia.

(6.) By the action of ammonium hydrate on ethyl carbonate at  $180^\circ$  ( $356^\circ$  F.).

(7.) By heating ammonium carbonate in sealed tubes to  $130^\circ$  ( $266^\circ$  F.).

(8.) By the slow evaporation of an aqueous solution of hydrocyanic acid.

(9.) By the molecular transformation of its isomerid, ammonium isocyanate:

It is obtained :

(1.) *From the urine*.—Fresh urine is evaporated to the consistency of a syrup over the water-bath; the residue is cooled and mixed with an equal volume of colorless  $\text{HNO}_3$  of sp. gr. 1.42; the crystals are washed with a small quantity of cold  $\text{H}_2\text{O}$ , and dissolved in hot  $\text{H}_2\text{O}$ ; the solution is decolorized, so far as possible, without boiling, with animal charcoal, filtered, and neutralized with potassium carbonate; the liquid is then concentrated over the water-bath, and decanted from the crystals of potassium nitrate which separate; then evaporated to dryness over the water-bath, and the residue extracted with strong, hot alcohol; the alcoholic solution, on evaporation, leaves the urea more or less colored by urinary pigment.

(2.) *By synthesis*.—Urea is more readily obtained in a state of purity from potassium isocyanate. This is dissolved in cold  $\text{H}_2\text{O}$ , and dry ammonium sulphate is added to the solution. Potassium sulphate crystallizes out, and is separated by decanting the liquid, which is then evaporated over the water-bath, fresh quantities of potassium sulphate crystallizing and being separated during the first part of the evaporation; the dry residue is extracted with strong, hot alcohol; this, on evaporation, leaves the urea, which, by a second crystallization from alcohol, is obtained pure.

Urea crystallizes from its aqueous solution in long, flattened prisms, and by spontaneous evaporation of its alcoholic solution in quadratic prisms with octahedral ends. It is colorless and odorless; has a cooling, bitterish taste, resembling that of salt-petre; is neutral in reaction; soluble in one part of  $\text{H}_2\text{O}$  at  $15^\circ$  ( $59^\circ$  F.), the solution being attended with diminution of tempera-

ture : soluble in five parts of cold alcohol (sp. gr. 0.816) and in one part of boiling alcohol ; very sparingly soluble in ether. When its powder is mixed with that of certain salts, such as sodium sulphate, the Aq. of the salt separates, and the mass becomes soft or even liquid. When pure it is not deliquescent, but is slightly hygrometric. Fuses at  $130^{\circ}$  ( $266^{\circ}$  F.).

Heated a few degrees above  $130^{\circ}$  ( $266^{\circ}$  F.) urea boils, giving off ammonia and ammonium carbonate, and leaves a residue of ammelid,  $C_6H_5N_3O_3$ . When heated to  $150^{\circ}$ – $170^{\circ}$  ( $302^{\circ}$ – $338^{\circ}$  F.), it is decomposed, leaving a mixture of ammelid, cyanuric acid, and biuret :

If urea is maintained at  $150^{\circ}$ – $170^{\circ}$  ( $302^{\circ}$ – $338^{\circ}$  F.) for some time, a dry, grayish mass remains, which consists principally of cyanuric acid. In this reaction, the volatile products contain urea, not that that substance is volatile, but because a portion of the cyanuric acid and ammonia unite to regenerate urea by the reverse action to that given above.

Dilute aqueous solutions of urea are not decomposed by boiling ; but if the solution be concentrated, or the boiling prolonged for a long time, the urea is partially decomposed into  $\text{CO}_2$  and  $\text{NH}_3$ . The same decomposition takes place more rapidly and completely when a solution of urea is heated under pressure to  $140^{\circ}$  ( $284^{\circ}$  F.). A pure aqueous solution of urea is not altered by exposure to filtered air. If urine be allowed to stand, putrefactive changes take place under the influence of a peculiar, organized ferment, or of a diastase-like body which is a constituent of normal urine.

Chlorin decomposes urea with production of  $\text{CO}_2$ , N, and HCl. Solutions of the alkaline hypochlorites and hypobromites effect a similar decomposition in the presence of an excess of alkali, according to the equation :

Upon this decomposition are based the quantitative processes of Knop, Hüfner, Yvon, Davy, Leconte, etc.

Nitrous acid, or  $\text{HNO}_3$  charged with nitrous vapors, decomposes urea according to the equation :

or the equation :

If the mixture be made in the cold, of one molecule of nitrogen trioxid to two molecules of urea, the decomposition is that indicated by Equation 2. If, on the other hand, the trioxid be gradually added to the previously warmed urea solution in the same proportion, half the urea is decomposed while the remainder is left unaltered, and, upon the addition of a further and sufficient quantity of the trioxid, all the urea is decomposed according to Equation 1. Upon this reaction are based the processes of Gréhant, Boymond, Draper, etc.

When heated with mineral acids or alkalis, urea is decomposed with formation of  $\text{CO}_2$  and  $\text{NH}_3$ ; if the decomposing agent be an acid,  $\text{CO}_2$  is given off, and an ammoniacal salt remains; if an alkali, a carbonate of the alkaline metal remains, and  $\text{NH}_3$  is given off. Upon this decomposition are based the processes of Heintz and Ragsky, Bunsen, etc.

Urea forms definite compounds, not only with acids, but also with certain oxids and salts. Of the compounds which it forms with acids, the most important are those with nitric and oxalic acids.

**Urea nitrate**— $\text{CON}_2\text{H}_4 \cdot \text{HNO}_3$ —is formed as a white, crystalline mass when a concentrated solution of urea is treated, in the cold, with  $\text{HNO}_3$ . It is much less soluble in  $\text{H}_2\text{O}$  than is urea, especially in the presence of an excess of  $\text{HNO}_3$ . It decomposes the carbonates with liberation of urea. If a solution of urea nitrate be evaporated over the water-bath, it is decomposed, bubbles of gas being given off beyond a certain degree of concentration, and large crystals of urea, covered with smaller ones of urea nitrate, separate.

**Urea oxalate**— $2\text{CON}_2\text{H}_4 \cdot \text{H}_2\text{C}_2\text{O}_4$ —separates as a fine, crystalline powder from mixed aqueous solutions of urea and oxalic acid of sufficient concentration. It is acid in taste and reaction, less soluble in cold  $\text{H}_2\text{O}$  than the nitrate, and less soluble in the presence of an excess of oxalic acid than in pure  $\text{H}_2\text{O}$ . Its solution may be evaporated at the temperature of the water-bath without suffering decomposition.

Of the compounds of urea with oxids, the most interesting are those with mercuric oxid, three in number :

a.  $\text{CON}_2\text{H}_4 \cdot 2\text{HgO}$  is formed by gradually adding mercuric oxid to a solution of urea, heated to near its boiling-point; the fil-

tered liquid, on standing twenty-four hours, deposits crystalline crusts of the above composition.

$\beta$ .  $\text{CON}_2\text{H}_4.3\text{HgO}$  is formed as a gelatinous precipitate when mercuric chlorid solution is added to a solution of urea containing potassium hydrate.

$\gamma$ .  $\text{CON}_2\text{H}_4.4\text{HgO}$  is formed as a white, amorphous precipitate when a dilute solution of mercuric nitrate is gradually added to a dilute alkaline solution of urea, and the excess of acid neutralized from time to time. A yellow tinge in the precipitate indicates the formation of mercuric subnitrate after the urea has been all precipitated (Liebig's process).

Of the compounds of urea with salts, that with sodium chlorid is the only one of importance :

$\text{CON}_2\text{H}_4.\text{NaCl}.\text{H}_2\text{O}$ .—It is obtained in prismatic crystals when solutions of equal molecules of urea and sodium chlorid are evaporated together. It is deliquescent and very soluble in water. Its solution, when mixed with solution of oxalic acid, only forms urea oxalate after long standing, or on evaporation.

Urea is a constant constituent of normal mammalian blood and urine, and is the chief product of the oxidation of albuminoid substances which occur in the body; the bulk of the N assimilated from the food ultimately making its exit from the body in the form of urea in the urine.

The determinations of the amount of urea in the blood and fluids other than the urine are, owing to imperfections in the processes of analysis, not as accurate as could be desired, the error being generally a minus one. Some of the more prominent are given in the following table :

QUANTITY OF UREA IN PARTS PER 1,000 IN ANIMAL FLUIDS  
OTHER THAN URINE.

Normal blood—dog.....	0.24-0.53	Munk.
Normal blood—human.....	0.2 -0.4	Gamgee.
Normal blood—human.....	0.16	Pickard.
Normal blood—human.....	0.14-0.18	Gautier.
Normal blood—human placental....	0.28-0.62	Picard.
Normal blood—human foetal.....	0.27	Picard.
Blood of dog before nephrotomy.....	0.26-0.88	Gréchant.
Blood of dog three hours after nephro- tomy.....	0.45-0.93	Gréchant.
Blood of dog twenty-seven hours after nephrotomy.....	2.06-2.76	Gréchant.
Human blood in cholera.....	2.4	Voit.
Human blood in cholera.....	3.6	Chalvet.
Human blood in Bright's.....	15.0	} Bright and } Babington.
Lymph—dog.....	0.16	Wurtz.
Lymph—cow.....	0.19	Wurtz.
Chyle—cow.....	0.19	Wurtz.
Milk ...	0.13	Picard.

Saliva.....	0.35	Picard.
Bile.....	0.30	Picard.
Fluid of ascites.....	0.15	Picard.
Perspiration .....	0.38	Funke.
Perspiration.....	0.88	Picard.

Under normal conditions, the quantity of urea voided in twenty-four hours is subject to considerable variations, as is shown in the subjoined table :

#### AMOUNT OF UREA IN HUMAN URINE—NORMAL.

	Parts per 1,000.	Grams in total urine of 24 hours.	
Urine of sp. gr. 1009.2.....	9.88	.....	Millon.

Urine of girl eighteen months old ....	.....	6-9	Harley.

The variations are produced by :

(1.) *Age*.—In new-born children the elimination of urea is insignificant. By growing children the amount voided is absolutely less than that discharged by adults, but, relatively to their weight, considerably greater; thus, Harley gives the following amounts of urea in grams for each pound of body-weight in twenty four hours: Boy, eighteen months, 0.4; girl, eighteen months, 0.35; man, twenty-seven years, 0.25; woman, twenty-seven years, 0.20. During adult life the mean elimination of urea remains stationary, unless modified by other causes than age.

In old age the amount sinks to below the absolute quantity discharged by growing children.

(2.) *Sex*.—At all periods of life females eliminate less urea than males. The proportion given by Beigel differs slightly from that of Harley, viz.: one kilo of male, 0.35 gram urea in twenty-four hours; one kilo of female, 0.25 gram. During pregnancy females discharge more urea than males; very shortly after delivery the amount sinks to the normal, below which it passes during lactation.

(3.) *Food*.—The quantity of urea eliminated is in direct proportion to the amount of N contained in the food. The ingestion of large quantities of watery drinks increases the amount, and a contrary effect is produced by tea, coffee, and alcohol. With insufficient food the excretion of urea is diminished, although not arrested, even in extreme starvation.

(4.) *Exercise*.—The question whether the elimination of urea is increased during violent muscular exercise is one which has been the subject of many observations and of much discussion. An examination of the various results shows that, while the excretion of urea is slightly greater during violent exercise than during periods of rest, the increase is so insignificant in comparison to the work done, and, in some instances, to the loss of body-weight, as to render the assumption that muscular force is the result of the oxidation of the nitrogenized constituents of muscle improbable. (See Gangee, "Physiological Chemistry," I., pp. 385-401, for a full review of the subject.)

The percentage of urea in the urine of the same individual is not the same at different times of the day. The minimum hourly elimination is in the morning hours; an increase begins immediately after the principal meal, and reaches its height in about six hours, when a diminution sets in and progresses to the time of the next meal. Gornup-Besanez gives a curve representing the hourly variations in the elimination of urea, which, reduced to figures, gives the following:

Hour.	Urea in Grams.	Hour.	Urea in Grams.	Hour.	Urea in Grams.
8-9 A.M. ....	1.5	4- 5 P.M. ....	2.6	12-1 A.M. ....	1.9
9-10 A.M. ....	1.5	5- 6 P.M. ....	3.1	1-2 A.M. ....	1.9
10-11 A.M. ...	1.4	6- 7 P.M. ....	2.8	2-3 A.M. ....	1.9
11 A.M.-12 M.	1.3	7- 8 P.M. ....	2.5	3-4 A.M. ....	1.8
12 M.-1 P.M..	1.8	8- 9 P.M. ....	2.3	4-5 A.M. ....	1.6
1-2 P.M. ....	1.9	9-10 P.M. ....	2.0	5-6 A.M. ....	1.6
2-3 P.M. ....	2.1	10-11 P.M. ....	2.0	6-7 A.M. ....	1.6
3-4 P.M. ....	2.3	11-12 P.M. ....	2.3	7-8 A.M. ....	1.5

The total of which, however, represents a quantity above the normal.

The absolute amount of urea eliminated in twenty-four hours is increased by the exhibition of diuretics, alkalies, colchicum, turpentine, rhubarb, alkaline silicates, and compounds of antimony, arsenic, and phosphorus. It is diminished by digitalis, caffein, potassium iodid, and lead acetate; not sensibly affected by quinin.

In acute febrile diseases both the relative and absolute amounts of urea eliminated augment, with some oscillations, until the fever is at its height. There is, however, no constant relation between the amount of urea eliminated and the body temperature. During the period of defervescence, the amount of urea eliminated in twenty-four hours is diminished below the normal; during convalescence it again slowly increases. If the malady terminate in death the diminution of urea is continuous to the end. In intermittent fever the amount of urea discharged is increased on the day of the fever and diminished during the interval. In cholera, during the algid stage, the elimination of urea by the kidneys is almost completely arrested, while the quantity in the blood is greatly increased. When the secretion of urine is again established, the excretion of urea is greatly increased (60–80 grams = 926–1235 grains a day), and the abundant perspiration is also rich in urea. In cardiac diseases, attended with respiratory difficulty, but without albuminuria, the elimination of urea is diminished and that of uric acid increased. In nephritis, attended with albuminuria, the elimination of urea at first remains normal; later it diminishes, and the urea, accumulating in the blood, has been considered by many as the cause of uræmic poisoning. It appears more probable, however, that the symptoms of uræmia are due to the retention in the blood of alkaloidal poisons normally excreted in small amount. The quantity of urea in the urine is also diminished in all diseases attended with dropsical effusions; but is increased when the dropsical fluid is reabsorbed. In true diabetes the amount of urea in the urine of twenty-four hours is greater than normal. In chronic diseases the elimination of urea is below the normal, owing to imperfect oxidation.

To detect the presence of urea in a fluid, it is mixed with three to four volumes of alcohol, and filtered, after having stood several hours in the cold; the filtrate is evaporated on the water-bath, and the residue extracted with strong alcohol; the filtered alcoholic fluid is evaporated, and the residue tested as follows:

(1.) A small portion is heated in a dry test-tube to about 160° (320° F.), until the odor of ammonia is no longer observed; the residue is treated with a few drops of caustic potassa solution and

one drop of cupric sulphate solution. If urea be present, the biuret resulting from its decomposition by heat causes the solution of the cupric oxid with a reddish-violet color. The same appearance is produced in solutions containing peptone.

(2.) A portion of the residue is dissolved in a drop or two of  $H_2O$ , and an equal quantity of *colorless* concentrated  $HNO_3$  added; if urea be present in sufficient quantity there appear white, shining, hexagonal or rhombic, crystalline plates or six-sided prisms of urea nitrate.

(3.) A portion dissolved in water, as in (2), is treated with a solution of oxalic acid; rhombic plates of urea oxalate crystallize.

**Determination of Quantity of Urea in Urine.**—It must not be forgotten that, in all quantitative determinations of constituents of the urine, the question to be solved is not how much of that constituent is contained in a given quantity of urine, but how much of that substance the patient is discharging in a given time, usually twenty-four hours. Quantitative determinations are, therefore, in most cases, barren of useful results, unless the quantity of urine passed by the patient in twenty-four hours is known; and, in view of diurnal variations in elimination, unless the urine examined be a sample taken from the *mixed urine of twenty-four hours*.

The process giving the most accurate results is that of Bunsen, in which the urea is decomposed into  $CO_2$  and  $NH_3$ , the former of which is weighed as barium carbonate. Unfortunately, this process requires an expenditure of time and a degree of skill in manipulation which render its application possible only in a well-appointed laboratory.

A process which is described in most text-books upon urinary analysis, and which is much used by physicians, is that of Liebig. As this method is one, however, which contains more sources of error than any other, and as it can only be made to yield approximately correct results by a very careful elimination, as far as possible, of those defects, it is not one which is adapted to the use of the physician.

Probably the most satisfactory process in the hands of the practitioner is that of Hüfner, based upon the reaction, to which attention was first called by Knop, of the alkaline hypobromites upon urea (p. 334); using, however, Dietrich's apparatus, or the more simple modification suggested by Rumpf, in place of that of Hüfner. The apparatus (Fig. 38) consists of a burette of 30-50 c.c. capacity, immersed in a tall glass cylinder filled with water, and supported in such a way as to admit of being raised or lowered at pleasure. The upper end of the burette communicates with the evolution bottle *a*, which has a capacity of 75 c.c., by means of a rubber tube.

The reagent required is made as follows: 27 c.c. of a solution of caustic soda, made by dissolving 100 grams  $NaHO$  in 250 c.c.  $H_2O$ , are brought into a glass-stoppered bottle, 2.5 c.c. bromin are added, the mixture shaken, and diluted with water to 150 c.c. The caustic soda solution may be kept in a glass-stoppered bottle

whose stopper is well paraffined, but the mixture must be made up as required, a fact which, owing to the irritating character of the Br vapor, renders the use of this reagent in a physician's office somewhat troublesome. The Br is best measured by a pipette of suitable size, having a compressible rubber ball at the upper end.

To conduct a determination, about 20 c.c. of the hypobromite solution are placed in the bottle *a*; 5 c.c. of the urine to be examined are placed in the short test-tube, which is then introduced into the position shown in the figure, care being had that no urine escapes. The cork with its fittings is then introduced, the pinch-cock *b* opened, and closed again when the level of liquid in the burette is the same as that in the cylinder. The decomposing vessel *q* is then inclined so that the urine and hypobromite solution mix; the decomposition begins at once, and the evolved N passes into the burette, which is raised from time to time so as to keep the external and internal levels of water about equal; the CO<sub>2</sub> formed is retained by the soda solution. In about an hour (the decomposition is usually complete in fifteen minutes, but it is well to wait an hour) the height is so adjusted that the inner and outer levels of water are exactly even, and the graduation is read, while the standing of the barometer and thermometer are noted at the same time.

In calculating the percentage of urea from the volume of N obtained, it is essential that a correction should be made for differences of temperature and pressure, without which the result from an ordinary sample of urine may be vitiated by an error of ten per cent. If, however, the temperature and barometric pressure have been noted, the correction is readily made by the use of the table (see Appendix B. III.), computed by Dietrich, giving the weight of 1 c.c. N at different temperatures and pressures.

In the square of the table in which the horizontal line of the observed temperature crosses the vertical line of the observed barometric pressure will be found the weight, in milligrams, of a c.c. of N; this, multiplied by the observed volume of N, gives the weight of N produced by the decomposition of the urea contained in 5 c.c. urine. But as 60 parts urea yield 28 parts N, the weight of N, multiplied by 2.14, gives the weight of urea in milligrams in

FIG 38.

5 c.c. urine. This quantity, multiplied by twice the amount of urine in 24 hours, and divided by 10,000, gives the amount of urea eliminated in 24 hours in grains. If the result be desired in grains the amount in grains is multiplied by 15.434.

*Example.*—5 c.c. urine decomposed; barometer = 736 mm.; thermometer = 10°; burette reading before decomposition = 64.2; same after decomposition = 32.6: c.c. N collected = 31.6. From the table 1 c.c. N at 10° and 736 mm BP weighs 1.1593. The patient passes 1500 c.c. urine in 24 hours:

$$31.6 \times 1.1593 = 36.6339 = \text{milligr. N in 5 c.c. urine.}$$

$$36.6339 \times 2.14 = 78.3965 = \text{milligr. urea in 5 c.c. urine.}$$

$$\frac{78.3965 \times 3000}{10,000} = 23.519 = \text{grams urea in 24 hours.}$$

$$23.519 \times 15.434 = 362.99 = \text{grains urea in 24 hours.}$$

In using this process it is well to have the urea solution as near the strength of one per cent. as possible; therefore if the urine be concentrated, it should be diluted. Even when carefully conducted, the process is not strictly accurate; creatinin and uric acid are also decomposed with liberation of N, thus causing a slight plus error: on the other hand, a minus error is caused by the fact that in the decomposition of urea by the hypobromite, the theoretical result is never obtained within about eight per cent. in urine. These errors may be rectified to a great extent by multiplying the result by 1.044.

A process which does not yield as accurate results as the preceding, but which is more easy of application, is that of Fowler, based upon the loss of sp. gr. of the urine after the decomposition of its urea by hypochlorite. To apply this method the sp. gr. of the urine is carefully determined, as well as that of the liq. sodæ chlorinatæ (Squibb's). One volume of the urine is then mixed with exactly seven volumes of the liq. sod. chlor., and, after the first violence of the reaction has subsided, the mixture is shaken from time to time during an hour, when the decomposition is complete; the sp. gr. of the mixture is then determined. As the reaction begins instantaneously when the urine and reagent are mixed, the sp. gr. of the mixture must be calculated by adding together once the sp. gr. of the urine and seven times the sp. gr. of the liq. sod. chlor., and dividing the sum by 8. From the quotient so obtained the sp. gr. of the mixture after decomposition is subtracted; every degree of loss in sp. gr. indicates 0.7791 gram of urea in 100 c.c. of urine. The sp. gr. determinations must all be made at the same temperature; and that of the mixture only when the evolution of gas has ceased entirely.

Finally, when it is only desired to determine whether the urea is greatly in excess or much below the normal, advantage may be taken of the formation of crystals of urea nitrate. Two samples of the urine are taken, one of 5 drops and one of 10 drops; the latter is evaporated, at a low temperature, to the bulk of the former, and cooled; to each, three drops of colorless  $\text{HNO}_3$  are added. If crystals do not form within a few moments in the concentrated sample, the quantity of urea is below the normal; if

they do in the unconcentrated sample, it is in excess. In using this very rough method, regard must be had to the quantity of urine passed in 24 hours; the above applies to the normal amount of 1200 c.c.: if the quantity be greater or less, the urine must be concentrated or diluted in proportion. The *amorphous* white ppt. caused by  $\text{HNO}_3$  in albuminous urine must not be mistaken for the *crystalline* deposit of urea nitrate.

### COMPOUND UREAS.

These compounds, which are exceedingly numerous, may be considered as formed by the substitution of one or more alcoholic or acid radicals for one or more of the remaining H atoms of urea.

Those containing alcoholic radicals may be obtained, as urea is obtained from ammonium isocyanate, from the cyanate of the corresponding compound ammonium: or by the action of  $\text{NH}_3$ , or of the compound ammonias, upon the cyanic ethers.

Those containing acid radicals have received the distinctive name of *ureids*. Some of them are derivatives of uric acid, which is itself probably an ureid. We will limit our consideration of these bodies to uric acid and the ureids obtained from and related to it.

**Uric acid—Lithic acid— $\text{C}_5\text{H}_2\text{N}_4\text{O}_6\text{H}_2$ —168.**—So far as yet known, uric acid is exclusively an animal product. It exists in the urine of man and of the carnivora, and in that of the herbivora when, during early life or starvation, they are for the time being carnivora; as a constituent of urinary calculi; and, very abundantly, in the excrement of serpents, tortoises, birds, mollusks, and insects, also in guano. It is present in very small quantity in the blood of man, more abundantly in that of gouty patients and in that of birds. The so-called "chalk-stones" deposited in the joints of gouty patients are composed of sodium urate. It also occurs in the spleen, lungs, liver, pancreas, brain, and muscular fluid.

Although uric acid may be obtained from calculi, urine, and guano, the source from which it is most readily obtained is the solid urine of large serpents, which is composed almost entirely of uric acid and the acid urates of sodium, potassium, and ammonium. This is dried, powdered, and dissolved in a solution of potassium hydrate: the solution is boiled until all odor of  $\text{NH}_3$  has disappeared. Through the filtered solution  $\text{CO}_2$  is passed, through a wide tube, until the precipitate, which was at first gelatinous, has become granular and sinks to the bottom: the acid potassium urate so formed is collected on a filter, and washed with cold  $\text{H}_2\text{O}$  until the wash-water becomes turbid when added to the first filtrate: the deposit is now dissolved in hot dilute caustic potassa solution, and the solution filtered hot into  $\text{HCl}$ , diluted with an equal volume of  $\text{H}_2\text{O}$ . The precipitated uric acid is washed and dried.

Uric acid, when pure, crystallizes in small, white, rhombic, rectangular or hexagonal plates, or in rectangular prisms, or in dendritic crystals of a hydrate,  $C_5H_4N_4O_3 \cdot 2H_2O$ . As crystallized from urine it is more or less colored with urinary pigments, and forms rectangular or rhombic plates, usually with the angles rounded so as to form lozenges, which are arranged in bundles, daggers, crosses, or dendritic groups, sometimes of considerable size. It is almost insoluble in  $H_2O$ , requiring for its solution 1900 parts of boiling  $H_2O$  and 15,000 parts of cold  $H_2O$ ; insoluble in alcohol and ether: its aqueous solution is acid to test-paper: cold  $HCl$  dissolves it more readily than  $H_2O$ , and on evaporation deposits it in rectangular plates. It is tasteless and odorless.

When heated, it is decomposed without fusion or sublimation. Its constitution is not established with certainty, although it is very probably the diureid of tartronic acid. Heated in  $Cl$  it yields cyanuric acid and  $HCl$ . When  $Cl$  is passed for some time through  $H_2O$  holding uric acid in suspension, alloxan, parabanic and oxalic acids, and ammonium cyanate are formed. Similar decomposition is produced by  $Br$  and  $I$ . It is simply dissolved by  $HCl$ . It is dissolved by  $H_2SO_4$ : from a hot solution in which a deliquescent, crystalline compound,  $C_5H_4N_4O_3 \cdot 4H_2SO_4$  is deposited: it is partly decomposed by  $H_2SO_4$  at  $140^\circ$  ( $284^\circ F.$ ). It dissolves in cold  $HNO_3$  with effervescence and formation of alloxan, alloxantin, and urea: with hot  $HNO_3$  parabanic acid is produced. Solutions of the alkalis dissolve uric acid with formation of neutral urates. Uric acid is dibasic.

**Ammonium urates.**—The neutral salt,  $C_5H_2N_4O_3(NH_4)_2$ , is unknown. The acid salt,  $C_5H_3N_4O_3(NH_4)$ , exists as a constituent of the urine of the lower animals, and occurs, accompanying other urates and free uric acid, in urinary sediments and calculi. Sediments of this salt are rust-yellow or pink in color, amorphous, or composed of globular masses, set with projecting points, or elongated dumb-bells, and are formed in alkaline urine. It is very sparingly soluble in  $H_2O$ : soluble in warm  $HCl$ , from which solution crystalline plates of uric acid are deposited.

**Potassium urates.**—The neutral salt,  $C_5H_2N_4O_3K_2$ , is obtained when a solution of potassium hydrate, free from carbonate, is saturated with uric acid: the solution on concentration deposits the salt in fine needles. It is soluble in 44 parts of cold  $H_2O$  and in 35 parts of boiling  $H_2O$ . It is alkaline in taste, and absorbs  $CO_2$  from the air.

The acid salt,  $C_5H_3N_4O_3K$ , is formed as a granular (at first gelatinous) precipitate when a solution of the neutral salt is treated with  $CO_2$ . It dissolves in 800 parts of cold  $H_2O$  and in 80 parts of boiling  $H_2O$ . The occurrence of potassium urates in urinary sediments and calculi is very exceptional.

**Sodium urates.**—The neutral salt,  $C_5H_2N_4O_7Na_2$ , is formed under similar conditions as the corresponding potassium salt. It forms nodular masses, soluble in 77 parts of cold  $H_2O$  and in 75 of boiling  $H_2O$ ; it absorbs  $CO_2$  from the air.

The acid salt,  $C_5H_3N_4O_8Na$ , is formed when the neutral salt is treated with  $CO_2$ . It is soluble in 1200 parts of cold  $H_2O$  and in 125 parts of boiling  $H_2O$ . It occurs in urinary sediments and calculi, very rarely crystallized. The arthritic calculi of gouty patients are almost exclusively composed of this salt, frequently beautifully crystallized.

**Calcium urates.**—The neutral salt,  $C_5H_2N_4O_7Ca$ , is obtained by dropping a solution of neutral potassium urate into a boiling solution of calcium chlorid until the precipitate is no longer redissolved, and then boiling for an hour. A granular powder, soluble in 1500 parts of cold  $H_2O$  and in 1440 parts of boiling  $H_2O$ .

The acid salt,  $(C_5H_3N_4O_8)_2Ca$ , is obtained by decomposing a boiling solution of acid potassium urate with calcium chlorid solution. It crystallizes in needles, soluble in 603 parts of cold  $H_2O$  and in 276 parts of boiling  $H_2O$ . It occurs occasionally in urinary sediments and calculi, and in "chalk-stones."

**Lithium urates.**—The acid salt,  $C_5H_3N_4O_8Li$ , is formed by dissolving uric acid in a warm solution of lithium carbonate. It crystallizes in needles, which dissolve in 60 parts of  $H_2O$  at  $50^\circ$  ( $122^\circ F.$ ) and do not separate when the solution is cooled. It is partly with a view to the formation of this, the most soluble of the acid urates, that the compounds of lithium are given to patients suffering with the uric acid diathesis.

Uric acid exists in the economy chiefly in combination as its sodium salts: it is occasionally found free, and from the probable method of its formation it is difficult to understand how all the uric acid in the economy should not have existed there free, at least at the instant of its formation. It can scarcely be doubted that uric acid is one of the products of the oxidation of the albuminoid substances—an oxidation intermediate in the production of urea; and that consequently diseases in which there is an excessive formation of uric acid, such as gout, have their origin in defective oxidation.

In human urine the quantity of uric acid varies with the nature of the food in the same manner as does urea, and in about the same proportion:

	Urea.	Uric Acid.	Proportion of Uric Acid to Urea.
Animal food.....	71.5	1.25	57.2
Mixed food.....	37.0	0.76	48.7
Vegetable food.....	26.0	0.50	52.0
Non-nitrogenized food ....	16.0	0.34	47.0

The mean elimination of uric acid in the urine is from one-thirty-fifth to one-sixtieth of that of urea, or about 0.5 to 1.0 gram (7.7-15.4 grains) in twenty-four hours. With a strictly vegetable diet the elimination of twenty-four hours may fall to 0.3 gram (4.6 grains), and with a surfeit of animal food it may rise to 1.5 gram (23 grains). The hourly elimination is increased after meals, and diminished by fasting and by muscular and mental activity.

Deposits of free uric acid occur in acid, concentrated urines. In gout the proportion of uric acid in the urine is diminished, although, owing to the small quantity of urine passed, it may be relatively great; during the paroxysms the quantity of uric acid is increased, both relatively and absolutely. The proportion of uric acid in the blood is invariably increased in gout.

Uric acid may be recognized by its crystalline form and by the **murexid test**. The substance is moistened with  $\text{HNO}_3$ , which is evaporated nearly to dryness at a low temperature; the cooled residue is then moistened with ammonium hydrate solution. If uric acid be present, a yellow residue—sometimes pink or red when the uric acid was abundant—remains after the evaporation of the  $\text{HNO}_3$ , and this, on the addition of the alkali, assumes a rich purplish-red color.

To detect uric acid in the blood, about two drachms of the serum are placed in a flat glass dish and faintly acidulated with acetic acid; a very fine fibril of linen thread is placed in the liquid, which is set aside and allowed to evaporate to the consistency of a jelly; the fibril is then examined microscopically. If the blood contain uric acid in abnormal proportion, the thread will have attached to it crystals of uric acid.

The best method for the determination of the quantity of uric acid in urine is the following: 250 c.c. of the filtered urine are acidulated with 10 c.c. of  $\text{HCl}$ , and the mixture set aside for twenty-four hours in a cool place. A small filter is washed, first with dilute  $\text{HCl}$  and then with  $\text{H}_2\text{O}$ , dried at 100 (212 F.), and weighed. At the end of twenty-four hours this filter is moistened in a funnel, and the crystals of uric acid collected upon it (those which adhere to the walls of the precipitating vessel are best separated by a small section of rubber tubing passed over the end of a glass rod, and used as a brush). No  $\text{H}_2\text{O}$  is to be used in this part of the process, the filtered urine being made use of to bring all the crystals upon the filter. The deposit on the filter is now washed with 35 c.c. of pure  $\text{H}_2\text{O}$ , added in small portions at a time; the filter and its contents are then dried and weighed. The difference between this weight and that of the dry filter alone is the weight of uric acid in 250 c.c. of urine. If from any cause more than 35 c.c. of wash-water have been used, (0.001 gr., 0.043 must be added to this weight for every c.c. of extra wash-water.

If the urine contain albumen, this must first be separated by adding two or three drops of acetic acid, heating to near 100° (212 F.), until the coagulum becomes flocculent, and filtering.

**Ureids derived from Uric Acid.**—These substances are quite numerous, and are divisible into ureids, diureids, triureids, and uræmic acids, according as they are formed by substitution in one, two, or three molecules of urea, and according as the acid radical substituted does or does not retain a group CQOH. Some of these substances require a brief mention :

**Oxalylurea—Parabanic acid**— $(\text{C}_2\text{O}_2)^{\text{CO}}_{\text{H}_2}$  }  $\text{N}_2$ —114—is urea in which two atoms of H have been replaced by the bivalent radical  $(\text{C}_2\text{O}_2)^{\text{CO}}$  of oxalic acid. It is obtained by oxidizing uric acid or alloxan by hot  $\text{HNO}_3$ .

**Allantoin**— $\text{C}_4\text{H}_6\text{N}_4\text{O}_3$ —130—occurs in the allantoinic fluid of the cow ; in the urine of sucking calves, in that of dogs and cats when fed on meat, in that of children during the first eight days of life, in that of adults after the ingestion of tannin, and in that of pregnant women. It is produced artificially by oxidizing uric acid, suspended in boiling  $\text{H}_2\text{O}$ , with lead dioxide.

It crystallizes in small, tasteless, neutral, colorless prisms ; sparingly soluble in cold  $\text{H}_2\text{O}$ , readily soluble in warm  $\text{H}_2\text{O}$ . Heated with alkalis it yields oxalic acid and  $\text{NH}_3$  ; and with dilute acids, **allanturic acid**,  $\text{C}_3\text{H}_4\text{N}_2\text{O}_3$ .

Allantoin has been obtained synthetically by heating together glyoxylic acid and urea.

**Mesoxalylurea—Alloxan**— $\text{C}_4\text{H}_2\text{N}_2\text{O}_4$ —142—is a product of the limited oxidation of uric acid. It has been found in the intestinal mucus in a case of diarrhœa. It forms colorless crystals, readily soluble in  $\text{H}_2\text{O}$ . It gradually turns red in air, and stains the skin red.

**Oxaluric acid**— $\text{C}_3\text{H}_4\text{N}_2\text{O}_4$ —132—occurs in its ammonium salt, as a normal constituent, in small quantity, in human urine. It may be obtained by heating oxalylurea with calcium carbonate.

It is a white, sparingly soluble powder, which is converted into urea and oxalic acid when boiled with water or alkalis. Its ammonium salt crystallizes in white, glistening, sparingly soluble needles. Its ready conversion into urea and oxalic acid and its formation from oxalylurea, itself a product of oxidation of uric acid, render it probable that oxaluric acid is one of the many intermediate products of the oxidation of the nitrogenous constituents of the body.

**Dialuric acid—Oxybarbituric acid**— $\text{C}_4\text{H}_4\text{N}_2\text{O}_4$ —a dibasic acid produced by reduction of alloxan.

**Alloxantin**— $\text{C}_4\text{H}_4\text{N}_2\text{O}_4$ —is a substance crystallizing in small, brilliant, very sparingly soluble prisms, produced by the action of reducing agents upon alloxan, whose action is less powerful than that required to convert alloxan into dialuric acid.

**Murexid—Ammonium purpurate**— $\text{C}_4\text{H}_4(\text{NH}_4)\text{N}_2\text{O}_6$ —is pro-

duced by oxidation of uric acid, of alloxan, and of a number of other derivatives of uric acid with subsequent contact of ammonium hydrate. It is supposed to be the ammonium salt of a hypothetical and non-isolated acid. The ammonium salt is of a brilliant, but evanescent purple color. (See Murexid test for uric acid, p. 846.)

**Hydurilic acid**— $\text{C}_5\text{H}_6\text{N}_4\text{O}_6$ —is produced as a yellowish, crystalline, sparingly soluble powder by heating together glycerin and dialuric acid. It is a strong dibasic acid.

**Violuric acid**— $\text{C}_4\text{H}_2\text{N}_4\text{O}_4$ —is produced, along with alloxan, by the action of nitric acid upon hydrilic acid. It forms small, readily soluble, octahedral crystals. It is a strong monobasic acid, whose salts are brilliantly colored.

**Carbamic acid**— $\text{N} \begin{smallmatrix} \text{H}_2 \\ \diagup \diagdown \\ \text{COOH} \end{smallmatrix}$ —The acid itself is unknown, but many of its salts and ethers have been obtained. The salts are much less stable than the ethers. Of the latter, one has become of some medical importance, not only in itself but also in certain of its derivatives.

**Ethyl carbamate—Urethan**— $\text{N} \begin{smallmatrix} \text{H}_2 \\ \diagup \diagdown \\ \text{COO.C}_2\text{H}_5 \end{smallmatrix}$ —is formed (1) by the action of cyanogen chlorid on alcohol; (2) by the action of alcohol upon urea nitrate under pressure at 120–130° (248–266° F.); (3) by the action of ethylcarbonic ether,  $\text{CO}_2(\text{C}_2\text{H}_5)_2$ , on alcohol. It forms thin, large, transparent, crystalline plates, fusible at about 50° (122° F.); boils at 180° (356° F.), very soluble in alcohol and in water.

**Chloral-urethan—Uralium—Somnal**— $\text{C}_7\text{H}_{12}\text{Cl}_3\text{O}_3\text{N}$  (?)—is a product obtained by the action of chloral upon urethan in the presence of ethylic alcohol. It is a very deliquescent, crystallizable solid, readily soluble in alcohol; decomposed by hot  $\text{H}_2\text{O}$  into chloral and urethan. It is questionable whether this is a definite compound or a mere mixture.

### TRIATOMIC ALCOHOLS.

These substances are known as **glycerins** or **glycerols**. Their relation to the monoatomic and diatomic alcohols is shown by the following formulæ:

They are obtained by the saponification of their ethers, either those existing in nature or those produced artificially.

They combine with acids to form three series of ethers, known as monoglycerids, diglycerids, and triglycerids, formed by the combination of one molecule of the alcohol with one, two, or three molecules of a monobasic acid.

**Glycerin—Glycerol—Propenyl Alcohol—Glycerinum (U. S.)— $C_3H_8(OH)_3$ —92**—was first obtained as a secondary product in the manufacture of lead plaster; it is now produced as a by-product in the manufacture of soaps and of stearin candles. It exists free in palm-oil and in other vegetable oils. It is produced in small quantity during alcoholic fermentation, and is consequently present in wine and beer. It is much more widely disseminated in its ethers, the neutral fats, in the animal and vegetable kingdoms.

It has been obtained by partial synthesis, by heating for some time a mixture of allyl tribromid, silver acetate and acetic acid, and saponifying the triacetin so obtained.

The glycerin obtained by the process now generally followed—the decomposition of the neutral fats and the distillation of the product in a current of superheated steam—is free from the impurities which contaminated the product of the older processes. The only impurity likely to be present is water, which may be recognized by the low sp. gr.

Glycerin is a colorless, odorless, syrupy liquid, has a sweetish taste; sp. gr. 1.26 at 15° (59° F.). Although it cannot usually be caused to crystallize by the application of the most intense cold, it does so sometimes under imperfectly understood conditions, forming small, white needles of sp. gr. 1.268, and fusible between 7° and 8° (44.6–46.4° F.). It is soluble in all proportions in water and alcohol, insoluble in ether and in chloroform. The sp. gr. of mixtures of glycerin and water increase with the proportion of glycerin. It is a good solvent for a number of mineral and organic substances (*glycerites* and *glyceroles*). It is not volatile at ordinary temperatures. When heated, a portion distils unaltered at 275–280° (527–536° F.), but the greater part is decomposed into acrolein, acetic acid, carbon dioxid, and combustible gases. It may be distilled unchanged in a current of superheated steam between 285° and 315° (545–599° F.), and distils under ordinary conditions when perfectly pure.

Concentrated glycerin, when heated to 150° (302° F.) ignites and burns without odor and without leaving a residue, and with a pale blue flame. It may also be burnt from a short wick.

Glycerin is readily oxidized, yielding different products with different degrees of oxidation. Platinum-black oxidizes it, with formation, finally, of  $H_2O$  and  $CO_2$ . Oxidized by manganese

dioxid and  $\text{H}_2\text{SO}_4$ , it yields  $\text{CO}_2$  and formic acid. If a layer of glycerin diluted with an equal volume of  $\text{H}_2\text{O}$  be floated on the surface of  $\text{HNO}_3$  of sp. gr. 1.5, a mixture of several acids is formed: oxalic,  $\text{C}_2\text{O}_4\text{H}_2$ ; glyceric,  $\text{C}_3\text{H}_6\text{O}_4$ ; formic,  $\text{CH}_2\text{O}_2$ ; glycollic,  $\text{C}_2\text{H}_4\text{O}_3$ ; glyoxylic,  $\text{C}_3\text{H}_4\text{O}_4$ ; and tartaric,  $\text{C}_4\text{H}_6\text{O}_6$ . When glycerin is heated with potassium hydrate, a mixture of potassium acetate and formiate is produced. When glycerin, diluted with 20 volumes of  $\text{H}_2\text{O}$ , is heated with  $\text{Br}$ ;  $\text{CO}_2$ , bromoform, glyceric acid, and  $\text{HBr}$  are produced. Phosphoric anhydrid removes the elements of  $\text{H}_2\text{O}$  from glycerin, with formation of acrolein (see p. 303). A similar action is effected by heating with  $\text{H}_2\text{SO}_4$ , or with potassium hydrosulphate. Heated with oxalic acid, glycerin yields  $\text{CO}_2$  and formic acid.

The presence of glycerin in a liquid may be detected as follows: Add  $\text{NaHO}$  to feebly alkaline reaction, and dip into it a loop of  $\text{Pt}$  wire holding a borax bead; then heat the bead in the blow-pipe flame, which is colored green if the liquid contain  $\frac{1}{100}$  of glycerin.

The glycerin used for medicinal purposes should respond to the following tests: (1) its sp. gr. should not vary much from that given above; (2) it should not rotate polarized light; (3) it should not turn brown when heated with sodium nitrate; (4) it should not be colored by  $\text{H}_2\text{S}$ ; (5) when dissolved in its own weight of alcohol, containing one per cent. of  $\text{H}_2\text{SO}_4$ , the solution should be clear; (6) when mixed with an equal volume  $\text{H}_2\text{SO}_4$ , of sp. gr. 1.83, it should form a limpid, brownish mixture, but should not give off gas.

### ACIDS DERIVABLE FROM THE GLYCERINS.

Three series of acids are derivable from the glycerins by substitution of  $\text{O}$  for  $\text{H}$ , in the group  $\text{CH}_2\text{OH}$ :

The terms of each series are triatomic: those of the glyceric series are monobasic, those of the tartronic series are dibasic, and those of the tricarballic series are tribasic.

**Malic acid**— $\text{C}_4\text{H}_6\text{O}_5$ —134—is the second term of the tartronic series, and is therefore dibasic. It exists in the vegetable kingdom; either free or combined with  $\text{K}$ ,  $\text{Na}$ ,  $\text{Ca}$ ,  $\text{Mg}$ , or organic bases; principally in fruits, such as apples, cherries, etc.; accompanied by citrates and tartrates.

It crystallizes in brilliant, prismatic needles; odorless; acid in taste; fusible at  $100^{\circ}$  ( $212^{\circ}$  F.); loses  $\text{H}_2\text{O}$  at  $140^{\circ}$  ( $284^{\circ}$  F.); deliquescent; very soluble in  $\text{H}_2\text{O}$  and in alcohol. Heated to  $175$ – $180^{\circ}$  ( $347$ – $356^{\circ}$  F.), it is decomposed into  $\text{H}_2\text{O}$  and maleic acid,  $\text{C}_4\text{H}_2\text{O}_4$ . The malates are oxidized to carbonates in the body.

### TRIBASIC UNSATURATED ACIDS.

**Aconitic Acid**— $\text{C}_6\text{H}_5(\text{COOH})_3$ —exists in its Ca salt in the different species of *aconitum* and of *equisetum*. It forms white, crystalline crusts, or by slow crystallization white plates or prisms; odorless; sour; soluble in water, alcohol and ether; fuses at  $186^{\circ}$  ( $366^{\circ}$ .8 F.). Its salts are soluble and crystalline. It is decomposed by heat into itaconic acid and  $\text{CO}_2$ .

**Chelidonic Acid**— $\text{C}_4\text{H}_4(\text{COOH})_3$ —crystallizes in sparingly soluble needles with 1 Aq. Exists in *Chelidonium majus*.

**Meconic Acid**— $\text{C}_4\text{H}_2\text{O}(\text{COOH})_3 \cdot 3\text{Aq}$ —is peculiar to opium, in which it exists in combination with a part, at least, of the alkaloids. It crystallizes in small prismatic needles; acid and astringent in taste; loses its Aq at  $120^{\circ}$  ( $248^{\circ}$  F.); quite soluble in water; soluble in alcohol; sparingly soluble in ether.

With ferric chlorid it forms a blood-red color, which is not discharged by dilute acids or by mercuric chlorid; but is discharged by stannous chlorid and by the alkaline hypochlorites.

### ETHERS OF GLYCERIN.

#### GLYCERIDS.

As glycerin is a triatomic alcohol, it contains three oxhydryl groups which may be removed, combining with H from an acid to form  $\text{H}_2\text{O}$ , and leaving a univalent, bivalent, or trivalent remainder, which may replace the H of monobasic acids to form three series of ethers. As, further, the OH groups differ from each other in that two of them are contained in the primary group  $\text{CH}_2\text{OH}$ , the other in the secondary group  $\text{CHOH}$ , there exist two isomeres of each mono- and di-glycerid:

Of the many substances of this class, only a few, principally those entering into the composition of the neutral fats, require consideration here.

**Tributylin**— $\text{C}_3\text{H}_5(\text{O}, \text{C}_4\text{H}_7\text{O})_3$ —302—exists in butter. It may also be obtained by heating glycerin with butyric acid and  $\text{H}_2\text{SO}_4$ . It is a pungent liquid, very prone to decomposition, with liberation of butyric acid.

**Trivalerin**— $\text{C}_3\text{H}_5(\text{O}, \text{C}_5\text{H}_9\text{O})_3$ —344—exists in the oil of some maritime mammalia, and is identical with the *phocenin* of Chevreul.

**Tricaproin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_6\text{H}_{11}\text{O})_3$ —386—**Tricaprylin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_8\text{H}_{17}\text{O})_3$ —470—and **Tricaprin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_{10}\text{H}_{19}\text{O})_3$ —554—exist in small quantities in milk, butter, and cocoa-butter.

**Tripalmitin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_{16}\text{H}_{33}\text{O})_3$ —806—exists in most animal and vegetable fats, notably in palm-oil; it may also be obtained by heating glycerin with 8 to 10 times its weight of palmitic acid for 8 hours at 250 (482° F.). It forms crystalline plates, very sparingly soluble in alcohol, even when boiling; very soluble in ether. It fuses at 50° (122° F.) and solidifies again at 46° (114.8° F.).

**Trimargarin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_{17}\text{H}_{33}\text{O})_3$ —848—has probably been obtained artificially as a crystalline solid, fusible at 60° (140° F.), solidifiable at 52° (125.6° F.). The substance formerly described under this name as a constituent of animal fats is a mixture of tripalmitin and tristearin.

**Tristearin**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_{18}\text{H}_{35}\text{O})_3$ —890—is the most abundant constituent of the solid fatty substances. It is prepared in large quantities as an industrial product in the manufacture of stearin candles, etc., but is obtained in a state of purity only with great difficulty.

In as pure a form as readily obtainable, it forms a hard, brittle, crystalline mass; fusible at 68° (154.4° F.), solidifiable at 61° (141.8° F.); soluble in boiling alcohol, almost insoluble in cold alcohol, readily soluble in ether.

**Triolein**— $\text{C}_8\text{H}_{17}\text{O}, \text{C}_{18}\text{H}_{33}\text{O})_3$ —884—exists in varying quantity in all fats, and is the predominant constituent of those which are liquid at ordinary temperatures; it may be obtained from animal fats by boiling with alcohol, filtering the solution, decanting after twenty-four hours' standing; freezing at 0° (32° F.), and expressing.

It is a colorless, odorless, tasteless oil; soluble in alcohol and ether, insoluble in water; sp. gr. 0.92.

**Trinitro-glycerin**—**Nitro-glycerin**— $\text{C}_3\text{H}_5(\text{ONO}_2)_3$ —227—used as an explosive, both pure and mixed with other substances, in dynamite, giant powder, etc., is obtained by the combined action of  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  upon glycerin. Fuming  $\text{HNO}_3$  is mixed with twice its weight of  $\text{H}_2\text{SO}_4$  in a cooled earthen vessel; 33 parts by weight of the mixed acids are placed in a porcelain vessel, and 5 parts of glycerin, of 31° Beaumé, are gradually added with constant stirring, while the vessel is kept well cooled; after five minutes the whole is thrown into 5-6 volumes of cold water; the

nitro-glycerin separates as a heavy oil, which is washed with cold water.

Nitro-glycerin is an odorless, yellowish oil; has a sweetish taste; sp. gr. 1.6; insoluble in water, soluble in alcohol and ether; not volatile; crystallizes in prismatic needles when kept for some time at  $0^{\circ}$  ( $32^{\circ}$  F.); fuses again at  $8^{\circ}$  ( $46^{\circ}.4$  F.).

When pure nitro-glycerin is exposed to the air at  $30^{\circ}$  ( $86^{\circ}$  F.) for some time, it decomposes, without explosion and with production of glyceric and oxalic acids. When heated to  $100^{\circ}$  ( $212^{\circ}$  F.) it volatilizes without decomposition; at  $185^{\circ}$  ( $365^{\circ}$  F.) it boils, giving off nitrous fumes; at  $217^{\circ}$  ( $422^{\circ}.6$  F.) it explodes violently; if quickly heated to  $257^{\circ}$  ( $494^{\circ}.6$  F.) it assumes the spheroidal form, and volatilizes without explosion. Upon the approach of flame at low temperatures it ignites and burns with slight decrepitations. When subjected to shock, it is suddenly decomposed into  $\text{CO}_2$ ;  $\text{N}$ ; vapor of  $\text{H}_2\text{O}$ , and  $\text{O}$ , the decomposition being attended with a violent explosion.

In order to render this explosive less dangerous to handle, it is now usually mixed with some inert substance, usually diatomaceous earth, in which form it is known as **dynamite**, etc.

When taken internally, nitro-glycerin is an active poison, producing effects somewhat similar to those of strychnin; in drop-doses, diluted, it causes violent headache, fever, intestinal pain, and nervous symptoms. It has been latterly used as a therapeutic agent, and has been used by the homœopaths under the name of **glonoin**.

### NEUTRAL OILS AND FATS.

These are mixtures in varying proportions of tripalmitin, tristearin, and triolein, with small quantities of other glycerids, coloring and odorous principles, which are obtained from animal and vegetable bodies. The oils are fluid at ordinary temperatures, the solid glycerids being in solution in an excess of the liquid triolein. The fats, owing to a less proportion of the liquid glycerid, are solid or semi-solid at the ordinary temperature of the air. Members of both classes are fluid at sufficiently high temperatures, and solidify when exposed to a sufficiently low temperature. They are, when pure, nearly tasteless and odorless, unctuous to the touch, insoluble in and not miscible with  $\text{H}_2\text{O}$ , upon which they float; combustible, burning with a luminous flame. When rubbed upon paper they render it translucent. When heated with the caustic alkalies, or in a current of superheated steam, they are **saponified**, *i.e.*, decomposed into glycerin and a fatty acid. If the saponification be produced by an alkali, the fatty acid combines with the alkaline metal to form a soap (*q.v.*).

Most of the fats and many of the oils, when exposed to the air, absorb O, are decomposed with liberation of volatile fatty acids, and acquire an acid taste and odor, and an acid reaction. A fat which has undergone these changes is said to have become rancid. Many of the vegetable oils are, however, not prone to this decomposition. Some of them, by oxidation on contact with the air, become thick, hard and dry, forming a kind of varnish over surfaces upon which they are spread; these are designated as **drying** or **siccative oils**. Others, although they become more dense on exposure to air, become neither dry nor gummy; these are known as **non-drying, greasy, or lubricating oils**.

Under ordinary conditions, oils and melted fats do not mix with water, and, if shaken with that fluid, form a *temporary* milky mixture, which, on standing for a short time, separates into two distinct layers, the oil floating on the water. In the presence, however, of small quantities of certain substances, such as albumen, pancreatin (*q.v.*), ptyalin, etc., the milky mixture obtained by shaking together oil and water does not separate into distinct layers on standing; such a mixture, in which the fat is held in a *permanent* state of suspension in small globules in a watery fluid, is called an **emulsion**. Good emulsions may be easily obtained by agitating an oil containing a trace of free oleic acid with a very dilute solution of sodium carbonate and borax.

**Fixed oils.**—These substances are designated as “fixed,” to distinguish them from other vegetable products having an oily appearance, but which differ from the true oils in their chemical composition and in their physical properties, especially in that they are volatile without decomposition, and are obtained by distillation, while the fixed oils are obtained by expression, with or without the aid of a gentle heat.

**Palm-oil** is a reddish-yellow solid at ordinary temperatures, has a bland taste and an aromatic odor. It saponifies readily, and is usually acid and contains free glycerin liberated by spontaneous decomposition.

**Rape-seed and colza oils**, produced from various species of *Brassica*, are yellow, limpid oils having a strong odor and disagreeable taste.

**Croton-oil—Oleum tiglii (U. S.)—Oleum crotonis (Br.)**—varies much in color and activity, according to its source: that which is obtained from the East is yellowish, liquid, transparent, and much less active than that prepared in Europe from the imported seeds, which is darker, less fluid, caustic in taste, and wholly soluble in absolute alcohol. Croton-oil contains, besides the glycerids of oleic, crotonic and fatty acids, about four per cent. of a peculiar principle called crotonol, to which the oil owes its vesi-

eating properties. It also contains an alkaloid-like substance, also existing in castor-oil, called ricinin. None of these bodies, however, are possessed of the drastic powers of the oil itself.

**Peanut-oil**—*Ground-nut-oil*—an almost colorless oil, very much resembling olive-oil, in place of which it is frequently used for culinary purposes, intentionally or otherwise. It is readily saponifiable, yielding two peculiar acids, arachaic and hypogaic (see Olive-oil).

**Cotton-seed-oil**—*Oleum gossypii seminis* (U. S.)—a pale yellow, bland oil, also resembling olive-oil, for which it is frequently substituted.

**Almond-oil**—*Oleum amygdalæ expressum* (U. S.)—*Oleum amygdalæ* (Br.)—a light yellow oil, very soluble in ether, soluble in alcohol; nearly inodorous; has a bland, sweetish taste. The pure oil has no odor of bitter almonds.

**Olive-oil**—*Oleum olivæ* (U. S., Br.)—a well-known oil of a yellow or greenish-yellow color, almost odorless, and of a bland and sweetish taste. The finest grades have a yellow tinge and a faint taste of the fruit; they are prepared by cold pressure; they are less subject to rancidity than the lower grades. Olive-oil is very frequently adulterated, chiefly with poppy-oil, sesame-oil, cotton-seed-oil and peanut-oil. The presence of the first is detected by Pontet's reagent (made by dissolving 6 parts Hg in 7.5 parts of  $\text{HNO}_3$  of 36° in the cold), which converts pure olive-oil into a solid mass, while an oil adulterated with a drying oil remains semi-solid. A contamination with oil of sesame is indicated by the production of a green color, with a mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ . Peanut-oil, an exceedingly common adulterant in this country, is recognized by the following method: ten grams of the oil are saponified; the soap is decomposed with HCl; the liberated fatty acids dissolved in 50 c.c. of strong alcohol; the solution precipitated with lead acetate; the precipitate washed with ether; the residue decomposed with hot dilute HCl; the oily layer separated and extracted with strong alcohol; the alcoholic fluid, on evaporation, yields crystals of arachaic acid, if the oil contains peanut-oil. The most usual adulteration is with cotton-seed-oil, which may be detected, if more than 5% be present, as follows: 10 c.c. each of the oil and of ethylic ether are agitated in a test-tube; add 5 c.c. strong solution of neutral lead acetate, and then 5 c.c. ammonium hydrate solution, and agitate again. In the presence of cotton-seed-oil an orange-red color is produced, particularly in the upper layer.

**Cocoa-butter**—*Oleum theobromæ* (U. S., Br.)—is, at ordinary temperatures, a whitish or yellowish solid of the consistency of tallow, and having an odor of chocolate and a pleasant taste; it does not easily become rancid. The most reliable test of its

purity is its fusing-point, which should not be much below  $33^{\circ}$  ( $91^{\circ}.4$  F.).

**Linseed-oil—Flaxseed-oil—Oleum lini (U. S., Br.)**—is a dark, yellowish-brown oil of disagreeable odor and taste. In it oleic acid is, at least partially, replaced by linoleic acid, whose presence causes the oil, on exposure to air, to absorb oxygen and become thick and finally solid. This drying power is increased by boiling the oil with litharge (boiled oil).

**Castor-oil—Oleum ricini (U. S., Br.)**—is usually obtained by expression of the seeds, although in some countries it is prepared by decoction or by extraction with alcohol. It is a thick, viscid, yellowish oil, has a faint odor and a nauseous taste. It is more soluble in alcohol than any other fixed vegetable oil, and is also very soluble in ether. It saponifies very readily. Ammonia separates from it a crystalline solid, fusible at  $66^{\circ}$  ( $158^{\circ}.8$  F.), ricinolamid. Hot  $\text{HNO}_3$  attacks it energetically, and finally converts it into *suberic acid*.

**Whale-oil—Train-oil**—obtained by *trying out* the fat or blubber of the "right whale" and of other species of *balaena*. It is of sp. gr. 0.924 at  $15^{\circ}$  ( $59^{\circ}$  F.); brownish in color; becomes solid at about  $0^{\circ}$ ; has a very nauseous taste and odor. It is colored yellow by  $\text{H}_2\text{SO}_4$ ; and is blackened by Cl.

**Neat's-foot-oil**—is obtained by the action of boiling  $\text{H}_2\text{O}$  upon the feet of neat cattle, horses, and sheep, deprived of the flesh and hoofs. It is straw-yellow or reddish-yellow, odorless, not disagreeable in taste, not prone to rancidity, does not solidify at quite low temperatures; sp. gr. at  $15^{\circ}$  ( $59^{\circ}$  F.) = 0.916. It is bleached, not colored, by chlorin.

**Lard-oil—Oleum adipis (U. S.)**—obtained in large quantities in the United States as a by-product in the manufacture of candles, etc., from pig's fat. A light yellow oil, used principally as a lubricant; is not colored by  $\text{H}_2\text{SO}_4$ , but is colored brown by a mixture of  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ .

**Tallow-oil**—obtained by expression with a gentle heat from the fat of the ox and sheep. Sp. gr. 0.9003; light yellow in color. Colored brown by  $\text{H}_2\text{SO}_4$ . Formerly this oil, under the trade name of "oleic acid," was simply a by-product in the manufacture of stearin candles; of late years, however, it is specially prepared for the manufacture of oleomargarine.

**Cod-liver-oil—Oleum morrhue (U. S., Br.)**—is obtained from the livers of cod-fish, either by extraction with water heated to about  $80^{\circ}$  ( $176^{\circ}$  F.), or by hanging the livers in the sun and collecting the oil which drips from them. There are three commercial varieties of this oil: (a) *Brown*.—Dark brown, with greenish reflections; has a disagreeable, irritating taste; faintly acid; does not solidify at  $-13^{\circ}$  ( $8^{\circ}.6$  F.). (b) *Pale brown*.—Of the color of Sherry

wine; has a peculiar odor and a fishy, irritating taste; strongly acid. (c) *Pale*.—(Golden yellow; deposits a white fat at  $-13^{\circ}$  ( $8.6^{\circ}$  F.); has a fresh odor, slightly fishy, and a not unpleasant taste, without after-taste.

Pure cod-liver-oil, with a drop of  $\text{H}_2\text{SO}_4$ , gives a bluish-violet aureole, which gradually changes to crimson, and later to brown. A drop of fuming  $\text{HNO}_3$  dropped into the oil is surrounded by a pink aureole if the oil be pure. If the oil be largely adulterated with other fish-oils, the pink color is not observed, and the oil becomes slightly cloudy. Fresh cod-liver-oil is not colored by rosanilin.

Cod-liver-oil contains, besides the glycerids of oleic, palmitic and stearic acids, those of butyric and acetic acids; certain biliary principles (to whose presence the sulphuric acid reaction given above is probably due), a phosphorized fat of undetermined composition; small quantities of bromine and iodine, probably in the form of organic compounds; a peculiar fatty acid called **gadinic acid**, which solidifies at  $60^{\circ}$  ( $140^{\circ}$  F.); and a brown substance called **gaduine** or **gadinin**. It also contains two alkaloids: **Asellin**,  $\text{C}_{26}\text{H}_{32}\text{N}_4$ , and **morrhuin**,  $\text{C}_{19}\text{H}_{27}\text{N}_3$ .

To which, if to any, of these substances cod-liver-oil owes its value as a therapeutic agent is still unknown, although many theories have been advanced. Certain it is, however, that one of the chief values of this oil is as a food in a readily assimilable form.

**Solid Animal Fats.**—The glycerids of stearic, palmitic, and oleic acids exist, in health, in nearly all parts of the body; in the fluids in solution or in suspension, in the form of minute oil-globules; incorporated in the solid or semi-solid tissues, or deposited in collections in certain locations, as under the skin, enclosed in cells of connective tissue.

The total amount of fat in the body of a healthy adult is from 2.5 to 5 per cent. of the body-weight, although it may vary considerably from that proportion in conditions not, strictly speaking, pathological. The approximate quantities of fat in 100 parts of the various tissues and fluids, in health, are the following:

Urine.....	?	Crystalline lens.....	2.0
Perspiration..	0.001	Liver.....	2.4
Vitreous humor.....	0.002	Muscle.....	3.3
Saliva.....	0.02	Hair.....	4.2
Lymph.....	0.05	Milk.....	4.3
Synovial fluid.....	0.06	Cortex of brain.....	5.5
Amniotic fluid.....	0.2	Brain.....	8.0
Chyle.....	0.3	Hen's egg.....	11.6
Mucus.....	0.4	White matter of brain....	20.0
Blood.....	0.4	Nerve-tissue.....	22.1
Cartilage.....	1.3	Spinal cord.....	23.6
Bone.....	1.4	Fat-tissue.....	82.7
Bile.....	1.4	Marrow.....	96.0

The amount of fat, under normal conditions, is usually greater in women and children than in men; generally greater in middle than in old age, although in some individuals the reverse is the case; greater in the inhabitants of cold climates than in those of hot countries.

In wasting from disease and from starvation the fats are rapidly absorbed, and are again as rapidly deposited when the normal condition of affairs is restored.

Besides, as a result of the tendency to corpulence, which in some individuals amounts to a pathological condition, fats may accumulate in certain tissues as a result of morbid changes. This accumulation may be due either to degeneration or to infiltration. In the former case, as when muscular tissue degenerates in consequence of long disuse, the natural tissue disappears and is replaced by fat; in the latter case, as in fatty infiltration of the heart, oil-globules are deposited between the natural morphological elements, whose change, however, may subsequently take place by true fatty degeneration, due to pressure. The greater part of the fat of the body enters it as such with the food. Not unimportant quantities are, however, formed in the body, and that from the albuminoid as well as from the starchy and saccharine constituents of the food. By what steps this transformation takes place is still uncertain, although there is abundant evidence that it does occur.

Those fats taken in with the food are unaltered by the digestive fluids, except in that they are freed from their enclosing membranes in the stomach, until they reach the duodenum. Here, under the influence of the pancreatic juice, the major part is converted into a fine emulsion, in which form it is absorbed by the lacteals. A smaller portion is saponified, and the products of the saponification, free fatty acids, soaps, and glycerin, subsequently absorbed by lacteals and blood-vessels.

The service of the fats in the economy is undoubtedly as a producer of heat and force by its oxidation; and by its low power of conducting heat, and the position in which it is deposited under the skin, as a retainer of heat produced in the body. The fats are not discharged from the system in health, except the excess contained in the food over that which the absorbents are capable of taking up, which passes out with the feces; a small quantity distributed over the surface in the perspiration and sebaceous secretion (which can hardly be said to be eliminated); and a mere trace in the urine.

**Butter.**—The fat of milk, separated and made to agglomerate by agitation, and more or less salted to insure its keeping. It consists of the glycerids of stearic, palmitic, oleic, butyric, capric, caprylic, and caproic acids, with a small amount of coloring mat-

ter, more or less water and salt, and casein. Good, natural butter contains 80-90 per cent. of fat, 6-10 per cent. of water, 2-5 per cent. of curd, and 2-5 per cent. of salt; fuses at from 32.8 to 34.9 (91°-94°.8 F.).

Butter is adulterated with excess of water and salt, starch, animal fats other than those of butter, and artificial coloring matters.

Excess of salt and water are usually worked in together, the former up to 14 per cent. and the latter to 15 per cent. To determine the presence of an excess of water, about 4 grains (60 grains) of the butter, taken from the middle of the lump, are weighed in a porcelain capsule, in which it is heated over the water-bath, as long as it loses weight; it is then weighed again; the loss of weight is that of the quantity of water in the original weight of butter, less that of the capsule. The proportion of salt is determined by incinerating a weighed quantity of butter and determining the chlorine in the ash by the nitrate of silver method (see Sodium chlorid). Roughly, the weight of the ash may be taken as salt. Starch is detected by spreading out a thin layer of butter, adding solution of iodine, and examining under the microscope for purple spots.

The detection of foreign fats in butter, formerly a most unsatisfactory problem to the analyst, has now become one which may be answered with great certainty. All of the chemical processes used are based upon a peculiar difference in the composition of butter-fat from other animal and vegetable fats and oils. When butter-fat is saponified, it yields from 5 to 8 per cent. of butyric acid and its near homologues, which are soluble in  $H_2O$ , and may be distilled without suffering decomposition, and from 85.5 to 87.5 of stearic, palmitic, and oleic acids, which are neither soluble in water nor capable of being distilled. The other fats and oils, when saponified, yield mere traces of the volatile or soluble fatty acids, and much larger quantities (95.3 to 95.7 per cent.) of insoluble acids. These variations are utilized directly in some processes, such as those of Helmer and Reichert, in which the percentage of fixed and volatile acids are directly determined. In other processes, such as those of Koettstorfer and Hübl, advantage is taken of the different neutralizing power of the two groups of acids. Thus, as butyric acid,  $C_4H_7O_2$ , and stearic acid,  $C_{18}H_{35}O_2$ , are each capable of neutralizing  $KHO$ , molecule for molecule, it follows that their neutralizing power is in proportion to their molecular weights, and that 56 parts  $KHO$  will require for neutralization 88 parts of butyric acid, or 284 parts of stearic acid. For descriptions of processes the student is referred to Allen, "Commercial Organic Analysis," 2d ed., II., pp. 145-160.

Methods for detecting admixture of foreign fats by physical means are unreliable. One of the best, which may be of service for preliminary testing, is that of Angell and Helmer. A pear-shaped bulb of thin glass is made of such size as to displace 1 c.c. water, is weighted with mercury until it weighs 3.4 grams (52.5 grains), and the pointed end closed by fusion. The butter to be tested is fused in a beaker over the water-bath, and when quite fluid is poured out into a test-tube about  $\frac{1}{4}$  inch diameter and 6 inches long, which is kept moderately warm and upright until the fat has separated in a clear layer above the water, and then immersed in water at 15 (59 F.) until the fat has solidified. The

test-tube is then arranged as shown in Fig. 39, the bulb being laid upon the surface of the fat. The water in the beaker is now heated until the globular part of the bulb has just sunk below the surface of the fat, at which time the height of the thermometer is noted; this is the "sinking-point."

FIG. 39.

The sinking-point of pure butter is  $34^{\circ}.3$  to  $36^{\circ}.3$  ( $93^{\circ}.7$ – $97^{\circ}.3$  F.), that of oleomargarine is lower, that of butter adulterated with other fats is higher.

"Oleomargarine" is a product made in imitation of butter, which it resembles very closely in color, taste, odor, and general appearance. Under the original patent, it is made from beef-fat, which is hashed, steamed, and subjected to pressure at a carefully regulated temperature. Under this treatment it is separated into two fatty products, one a white solid, "stearine," the other a faintly yellow oil, "oleo-oil." This oil is then mixed with milk, the mixture colored and churned. The subsequent treatment of the product is the same as that of butter. "Butterine," "suine," etc., are products made, by modifications of the above process, from beef or mutton tallow, lard, and cotton-seed-oil.

Butter is frequently, and oleomargarine is always, colored with some foreign pigment, "butter color," which is usually a preparation of annoto.

**Soaps**—are the metallic salts of stearic, palmitic, and oleic acids: those of K, Na, and  $\text{NH}_4$  are soluble, those of the other metals insoluble. Those of Na are hard, those of K soft.

Soap is made from almost any oil or fat, the best from olive-oil, or peanut, or palm-oil, and lard. The first step in the process of manufacture is the **saponification** of the fat, which consists in the decomposition of the glyceric ethers into glycerin and the fatty acids, and the combination of the latter with an alkaline metal. It is usually effected by gradually adding fluid fat to a weak boiling solution of caustic soda, or potassa, to saturation. From this weak solution the soap is separated by "salting," which consists in adding, during constant agitation, a solution of caustic alkali, heavily charged with common salt, until the soap separates in grumous masses, which float upon the surface and are separated. Finally the soap is pressed to separate adhering water, fused, and cast into moulds.

**White Castile soap**—**Sapo** (U. S.), **Sapo durus** (Br.)—is a Na soap made from olive-oil; strongly alkaline, hard, not greasy, very soluble; contains 21 per cent.  $\text{H}_2\text{O}$ . **Sapo mollis** (Br.) is a K soap

made from olive-oil, and contains an excess of alkali and glycerin. **Yellow soap** is made from tallow or other animal fat, and contains about  $\frac{1}{2}$  its weight of rosin. **Emplastrum plumbi** (U. S., Br.) is a lead soap, prepared by saponifying olive-oil with litharge.

The soaps are decomposed by weak acids, with liberation of the fatty acid; by compounds of the alkaline earths, with formation of an insoluble soap; and in the same way by most of the metallic salts.

### LECITHINS—NERVE-TISSUE.

**Lecithin**—is a substance first obtained from the yolk of hens' eggs, and subsequently found to exist in brain-tissue, particularly the gray substance, nerve-tissue, semen, blood-corpuscles, blood-serum, milk, bile, and other animal tissues and fluids.

As obtained from brain-tissue lecithin is a colorless or faintly yellowish, imperfectly crystalline solid, or sometimes of a waxy consistency. It is very hygroscopic. It does not dissolve in  $H_2O$ , in which, however, it swells up and forms a mass like starch-paste. It dissolves in alcohol or ether, very sparingly in the cold, but readily under the influence of heat. It dissolves in chloroform and in benzol. Lecithin is very prone to decomposition, particularly at slightly elevated temperatures. Its chlorid combines with  $PtCl_4$  to form an insoluble yellowish chloroplatinate.

When an alcoholic solution of lecithin is brought into contact with hot solution of barium hydrate it yields barium glycerophosphate, barium stearate, and cholin (see p. 276). This decomposition indicates the constitution of lecithin and its relations to the fats. Glycerophosphoric acid is phosphoric acid in which an atom of hydrogen has been replaced by the univalent remainder  $CH_2OH-CHOH-CH_2-$  left by the removal of  $OH$  from glycerin;

In lecithin the remaining oxhydriyl groups of the glycerin remainder are removed by union with the basic hydrogen of two molecules of stearic acid, and one of the two remaining basic hydrogen atoms of the phosphoric acid is displaced by cholin. It is obvious that the number of lecithins is not limited to one, but that many may exist, and probably do, into whose composition any one, or any combination of two, of the acids of the same series as stearic acid may enter

**Nerve-tissue**, which is exceedingly complex in its chemical composition, and whose chemistry is still in a most rudimentary condition, seems to contain similar constituents in its different parts, which differ, however, materially in their quantitative composition.

The following substances have been obtained from cerebral tissue:

*Mineral Substances.*

Water.  
Phosphates of Na, K, Ca, Mg.  
Ferric oxid.  
Silicic oxid.  
Traces of sulphates, chlorids,  
and fluorids.

*Products of Decomposition.*

Glycerophosphoric acid.  
Oleophosphoric acid.  
Volatile fatty acids.  
Lactates.  
Hypoxanthin.  
Xanthin.  
Creatin.

*Albuminoids.*

Substance related to myosin.  
Soluble albuminoid, coagulable at 75° (167° F.).  
Casein (?).

*Organic Substances.*

Elastin.	Lecithin.
Neurokeratin.	Fats (?).
Nuclein.	Inosite.
Cerebrin.	Cholesterin.

The composition of white and gray matter differs quantitatively, as shown below:

	Gray Matter.	White Matter.
Albuminoids .....	55.37	24.72
Lecithin .....	17.24	9.90
Cholesterin and fats .....	18.68	51.91
Cerebrin. ....	0.53	9.55
Extractive matters, insoluble in ether...	6.71	3.34
Salts.....	1.46	0.57

**Cerebrin** is a substance deposited in the crystalline form from hot ethero-alcoholic extracts of brain-tissue. It is white, very light, odorless, and tasteless; insoluble in water or in cold alcohol or ether. Its solutions are neutral. It does not contain phosphorus.

The substance known as **protagon**, described by Liebreich as having been obtained from brain-tissue, would seem to exist there notably in the white substance of Schwann. It appears to be a compound formed by the union of lecithin with cerebrin.

**Neurokeratin** is a substance occurring principally in the gray matter, which is insoluble in all solvents, and is not acted upon by digestive liquids.

## DIAMIDS OF THE TARTRONIC SERIES.

**Amids of malic acid.**—Malic acid may yield five amids, whose relations to the acid and to each other are shown by the following formulæ:

**Malamic acid**—is not known free, but exists as its ethylic ether in **malamethan**.

**Aspartic acid**—occurs in the molasses from beet-sugar, and is produced by the decomposition of asparagin by acids or alkalies. It crystallizes in sparingly soluble prisms.

**Malamid**—is produced in large crystals, by the action of excess of  $\text{NH}_3$  on dry ethyl malate.

**Asparagin**—is quite widely disseminated in vegetable nature, and is best obtained from asparagus, from the root of the marsh-mallow, or from vetches. It crystallizes in orthorhombic prisms with 1 Aq; sparingly soluble in water, odorless, faintly nauseous in taste, faintly acid in reaction. Its solutions are levogyrous  $[\alpha]_D^{25} = 35-38^\circ$ . It enters into unstable combination with both acids and bases. It is converted into aspartic acid and ammonia by heating with dilute mineral acids or alkaline solutions. It is not oxidized by  $\text{HNO}_3$  unless the acid contain nitrogen oxids, in which case it decomposes asparagin into malic acid, N, and  $\text{H}_2\text{O}$ .

## THIRD SERIES OF HYDROCARBONS.

SERIES  $C_nH_{2n-2}$ .

The hydrocarbons of this series, above the first, form two isomeric series, designated as *alpha* and *Beta*. Those of the *alpha* series are produced by heating the dibromids or diiodids of the olefins with alcoholic solution of KHO. They have the general formula  $HC \equiv C - C_nH_{2n+1}$ . Those of the *Beta* series are produced by a variety of reactions, and have the general formula  $H_2C = C = C_nH_{2n}$ .

**Acetylene—Ethine— $C_2H_2$ —26**—exists in coal-gas, and is formed in the decomposition, by heat or otherwise, of many organic substances. It is best prepared by passing a slow current of coal-gas through a narrow tube, traversed by induction sparks; directing the gas through a solution of cuprous chlorid; and collecting and decomposing the precipitate by HCl. It may be obtained by direct synthesis from H and C, by producing the electric arc between carbon points in a glass globe filled with hydrogen.

It is a colorless gas, rather soluble in  $H_2O$ ; has a peculiar, disagreeable odor; such as is observed when a Bunsen burner burns within the tube. It forms explosive mixtures with O. It unites with N, under the influence of the electric discharge, to form hydrocyanic acid. Mixed with Cl, it detonates violently in diffuse daylight, without the aid of heat. It may be made to unite with itself to form its polymeres benzene,  $C_6H_6$ , styrolene,  $C_8H_6$ , and naphthydrene,  $C_{10}H_{10}$ .

Its presence may be detected by the formation in an ammoniacal solution of cuprous chlorid of a blood-red precipitate, which is explosive when dry. It is probable that explosions which sometimes occur in brass or copper pipes, through which illuminating gas is conducted, are due to the formation of this compound.

**Illuminating gas**—is now manufactured by a variety of processes; thus we have gas made from wood, from coal, from fats, from petroleum, and by the decomposition of  $H_2O$  and subsequent charging of the gas with the vapor of naphtha. The typical process is that in which the gas is produced by heating bituminous coal to bright redness in retorts. As it issues from the retorts the gas is charged with substances volatile only at high temperatures; these are deposited in the condensers or coolers, and form coal- or gas-tar. From the condensers the gas passes through what are known as "scrubbers" and "lime-purifiers," in which it is deprived of ammoniacal compounds and other impurities. As it comes from the condensers, coal-gas contains:

* Acetylene.	* Acenaphthalene.	† Cyanogen.
* Ethylene.	* Fluorene.	† Sulphocyanogen.
* Marsh-gas.	* Propyl hydrid.	† Hydrogen sulphid.
* Butylene.	* Butyl hydrid.	† Carbon disulphid.
* Propylene.	† Hydrogen.	† Sulphuretted hydrocarbons.
* Benzene.	† Carbon monoxid.	† Nitrogen.
* Styrolene.	† Carbon dioxid.	† Aqueous vapor.
* Naphthalene.	† Ammonia.	

In passing through the purifiers the gas is freed of the impurities to a greater or less extent, and, as usually delivered to consumers, contains:

* Marsh-gas.	† Hydrogen.	† Carbon monoxid.
* Acetylene.	† Nitrogen.	† Carbon dioxid.
* Ethylene.	† Aqueous vapor.	* Vapors of hydrocarbons.

### TETRATOMIC ALCOHOLS.

#### SERIES $C_nH_{2n+2}O_4$ .

Very few of these compounds have yet been obtained. They may be regarded as the hydrates of the hydrocarbons  $C_nH_{2n+2}$ ; as the glycols are the hydrates of the ethylene series.

decomposition of erythrin,  $C_{20}H_{22}O_{10}$ , which exists in the lichens of the genus *rocella*. It crystallizes in large, brilliant prisms; very soluble in  $H_2O$  and in hot alcohol, almost insoluble in ether; sweetish in taste; its solutions neither affect polarized light, nor reduce Fehling's solution, nor are capable of fermentation. Its watery solution, like that of sugar, is capable of dissolving a considerable quantity of lime, and from this solution alcohol precipitates a definite compound of erythrite and calcium. By oxidation with platinum-black it yields erythroglucic acid,  $C_4H_6O_5$ . With fuming  $HNO_3$  it forms a tetranitro compound, which explodes under the hammer.

### ACIDS DERIVABLE FROM ERYTHRITE.

Theoretically erythrite should, by simple oxidation, yield two acids: one of the series  $C_nH_{2n}O_5$ , and another of the series  $C_nH_{2n-2}O_6$ . Although both of these acids are known, only the first, *erythroglucic acid*, has been obtained by oxidation of erythrite:

\* Illuminating constituents.

† Impurities.

‡ Diluent.

Erythrite.

Erythroglucic acid.

Tartaric acid.

**Tartaric acids**—**Acidum tartaricum** (U. S., Br.)— $\text{C}_4\text{H}_6\text{O}_6$ —150.—There exist four acids having the composition  $\text{C}_4\text{H}_6\text{O}_6$ , which differ from each other only in their physical properties, and are very readily converted into one another; they are designated as: 1st, **Right**; 2d, **Left**; 3d, **Inactive tartaric acid**; 4th, **Racemic acid**.

**Right** or **dextrotartaric acid** crystallizes in large, oblique, rhombic prisms, having hemihedral facettes. Solutions of the acid and its salts are dextrogyrous.

**Lævotartaric acid** crystallizes in the same form as dextrotartaric acid, only the hemihedral facettes are on the opposite sides, so that crystals of the two acids, when held facing each other, appear like the reflections one of the other. Its solutions and those of its salts are lævogyrous to the same degree that corresponding solutions of dextrotartaric acid are dextrogyrous. **Racemic acid** is a compound of the two preceding; it forms crystals having no hemihedral facettes, and its solutions are without action on polarized light. It is readily separated into its components. **In-active tartaric acid**, although resembling racemic acid in its crystalline form and inactivity with respect to polarized light, differs essentially from that acid in that it cannot be decomposed into right and left acids, and in the method of its production.

The tartaric acid which exists in nature is the dextrotartaric. It occurs, both free and in combination, in the sap of the vine and in many other vegetable juices and fruits. Although this is probably the only tartaric acid existing in nature, all four varieties may and do occur in the commercial acid, being formed during the process of manufacture.

Tartaric acid is obtained in the arts from hydropotassic tartrate, or cream of tartar (*q. v.*). This salt is dissolved in  $\text{H}_2\text{O}$  and the solution boiled with chalk until its reaction is neutral; calcic and potassic tartrates are formed. The insoluble calcic salt is separated and the potassic salt decomposed by treating the solution with calcic chlorid. The united deposits of calcium tartrate are suspended in  $\text{H}_2\text{O}$ , decomposed with the proper quantity of  $\text{H}_2\text{SO}_4$ , the solution separated from the deposit of calcium sulphate, and evaporated to crystallization.

The ordinary tartaric acid crystallizes in large prisms; very soluble in  $\text{H}_2\text{O}$  and alcohol; acid in taste and reaction. It fuses

at 170° (338° F.); at 180° (356° F.) it loses  $H_2O$ , and is gradually converted into an anhydrid; at 200–210° (392–410° F.) it is decomposed with formation of pyruvic acid,  $C_3H_4O_3$ , and pyrotartaric acid,  $C_8H_6O_4$ ; at higher temperatures  $CO_2$ ,  $CO$ ,  $H_2O$ , hydrocarbons and charcoal are produced. If kept in fusion some time, two molecules unite, with loss of  $H_2O$ , to form tartralic or ditartaric acid,  $C_8H_{10}O_{11}$ .

Tartaric acid is attacked by oxidizing agents with formation of  $CO_2$ ,  $H_2O$ , and, in some instances, formic and oxalic acids. Certain reducing agents convert it into malic and succinic acids. With fuming  $HNO_3$  it forms a dinitro-compound, which is very unstable, and which, when decomposed below 36° (96.8° F.), yields tartaric acid. It forms a precipitate with lime-water, soluble in an excess of  $H_2O$ . In not too dilute solution it forms a precipitate with potassium sulphate solution. It does not precipitate with the salts of  $Ca$ . When heated with a solution of auric chlorid it precipitates the gold in the metallic form. As its formula indicates (see above), tartaric acid is tetratomic and dibasic. It has a great tendency to the formation of double salts, such as tartar emetic (*q.v.*).

When taken into the economy, as it constantly is in the form of tartrates, the greater part is oxidized to carbonic acid (carbonates); but, if taken in sufficient quantity, a portion is excreted unchanged in the urine and perspiration. The free acid is poisonous in large doses.

**Citric acid—***Acidum citricum* (U. S., Br.)— $C_6H_8O_7 + Aq - 192 + 18$ —is best considered in this place, although its constitution is different from that of tartaric acid. It exists in the juices of many fruits—lemon, strawberry, etc., and in cows' milk in the proportion of about 0.1%, as calcium citrate.

It is obtained from lemon-juice, which is filtered, boiled, and saturated with chalk. The insoluble calcium citrate is separated and decomposed with  $H_2SO_4$ , the solution filtered, and evaporated to crystallization.

It crystallizes in large, right rhombic prisms, which lose their aq at 100° (212° F.); very soluble in water, less soluble in alcohol, sparingly soluble in ether; heated to 100° (212° F.) it fuses; at 175° (347° F.) it is decomposed, with loss of  $H_2O$  and formation of *aconitic acid*,  $C_6H_6O_6$ ; at a higher temperature  $CO_2$  is given off, and *itaconic acid*,  $C_5H_6O_4$ , and *citraconic acid*,  $C_5H_6O_4$ , are formed.

Concentrated  $H_2SO_4$  decomposes it with evolution of  $CO$ ; oxidizing agents convert it into formic acid and  $CO_2$ , or into acetone and  $CO_2$ , or into oxalic and acetic acids and  $CO_2$ . It is tetratomic and tribasic. In the body its salts are oxidized to carbonates.

Citric acid may be distinguished from tartaric and malic acids by the following reaction: Add glycerin, fuse in a porcelain cap-

sule, heat until acrolein is given off, dissolve in  $\text{NH}_4\text{HO}$ . Expel  $\text{NH}_4\text{HO}$  by heat, add two drops  $\text{HNO}_3$ —a green color, changing to blue when heated.

### HEXATOMIC ALCOHOLS.

The known terms of this series are isomeric; have the composition  $\text{C}_6\text{H}_{14}\text{O}_6$ . They are closely related to the carbohydrates.

**Mannite**—constitutes the greater part of *mannu*, and also exists in a number of other plants. It is also produced during the so-called mucic fermentation of sugar, and during lactic fermentation. It crystallizes in long prisms, odorless, sweet, fuses at  $166^\circ$  ( $330.8^\circ \text{F.}$ ) and crystallizes on cooling; boils at  $200^\circ$  ( $392^\circ \text{F.}$ ), at which temperature it is converted into mannitan,  $\text{C}_6\text{H}_{12}\text{O}_5$ ; soluble in  $\text{H}_2\text{O}$ , very sparingly in alcohol. When oxidized it yields first mannitic, then saccharic acid (*q.r.*), and finally, oxalic acid. Organic acids combine with it to form compound ethers.

**Dulcite**—**Melampyrite**—**Dulcose**—**Dulcin**—exists in *Melampyrum nemorosum*. It forms colorless, transparent prisms, fuses at  $182^\circ$  ( $359.6^\circ \text{F.}$ ), is odorless, faintly sweet, neutral in reaction, and optically inactive. It is subject to decompositions very similar to those to which mannite is subject, yielding dulcitan,  $\text{C}_6\text{H}_{12}\text{O}_5$ .

**Sorbite**—exists in the berries of the mountain ash. **Pinite**—exists in the sap of the California pine, and quercite in acorns.

### CARBOHYDRATES.

These substances are composed of C, H, and O; they all contain  $\text{C}_6$ , or some multiple thereof; and the H and O which they contain are always in the proportion of  $\text{H}_2$  to O. Their constitution are still unknown; probably some are aldehydes, others alcohols and others ethers. Most of them are constituents of animal or vegetable organisms, and have not been obtained by complete synthesis.

They are divisible into three groups, the members of each of which are isomeric with each other:

#### I. GLUCOSES.

- + Glucose.
- (Dextrose.)
- Lævulose.
- Mannitose.
- + Galactose.
- Inosite.
- Sorbin.
- Eucalin.

#### II. SACCHAROSES.

- + Saccharose.
- + Lactose.
- + Maltose.
- + Melitose.
- + Melezitose.
- + Trehalose.
- + Mycose.
- Synanthrose.
- + Parasaccharose.

#### III. AMYLOSES.

- + Starch.
- + Glycogen.
- + Dextrin.
- Inulin.
- Tunicin.
- Cellulose.
- Gums.

Glucoses,  $C_6H_{12}O_6$ —180.

**Glucose—Grape-sugar—Dextrose—Liver-sugar—Diabetic sugar.**

—The substance from which this group takes its name exists in all sweet and acidulous fruits; in many vegetable juices; in honey; in the animal economy in the contents of the intestines, in the liver, bile, thymus, heart, lungs, blood, and in small quantity in the urine. Pathologically it is found in the saliva, perspiration, feces, and largely increased in the blood and urine in diabetes mellitus (see below). It may also be obtained by decomposition of certain vegetable substances called *glucosids* (*q. v.*).

It is prepared artificially by heating starch or cellulose for 24 to 36 hours with a dilute mineral acid ( $H_2SO_4$ ). Glucose obtained by this method is liable to contamination with traces of arsenic, which it receives from the  $H_2SO_4$ . Starch is also converted into glucose by the influence of *diastase*, formed during the germination of grain.

Glucose crystallizes with difficulty from its aqueous solution, in white, opaque, spheroidal masses containing 1 aq; from alcohol in fine, transparent, anhydrous prisms. At about 60 (140 F.) in dry air the hydrated variety loses  $H_2O$ . It is soluble in all proportions in hot  $H_2O$ ; very soluble in cold  $H_2O$ ; soluble in alcohol. It is less sweet and less soluble than cane-sugar. Its solutions are dextrogyrous:  $[\alpha]_D = +52.85$ .

At 170 (338 F.) it loses  $H_2O$  and is converted into *glucosan*,  $C_6H_{10}O_5$ . Hot dilute mineral acids convert it into a brown substance, *ulmic acid*, and, in the presence of air, *formic acid*. It dissolves in concentrated  $H_2SO_4$ , without coloration, forming *sulphoglucic acid*. Cold concentrated  $HNO_3$  converts it into *nitroglucose*. Hot dilute  $HNO_3$  oxidizes it to a mixture of *oxalic* and *oxysaccharic acids*. With organic acids it forms ethers. Its solutions dissolve potash, soda, lime, baryta, and the oxids of Pb and Cu, with which it forms compounds. When its solutions are heated with an alkali they assume a yellow or brown color, and give off a molasses-like odor, from the formation of *glucic* and *melassic acids*. Glucose in alkaline solution exerts a strong reducing action, which is favored by heat; Ag, Bi, and Hg are precipitated from their salts; and cupric are reduced to cuprous compounds, with separation of cuprous oxid. In the presence of yeast, at suitable temperatures, glucose undergoes alcoholic fermentation.

**Physiological.**—The greater part of the glucose in the economy in health is introduced with the food, either in its own form or as other carbohydrates, which by digestion are converted into glucose. A certain quantity is also produced in the liver at the expense of glycogen, a formation which continues for some time

after death. In some forms of diabetes the production of glucose in the liver is undoubtedly greatly increased. The quantity of sugar normally existing in the blood varies from 0.81 to 1.231 part per thousand; in diabetes it rises as high as 5.8 parts per thousand.

Under normal conditions, and with food not too rich in starch and saccharine materials, the quantity of sugar eliminated as such is exceedingly small. It is oxidized in the body, and the ultimate products of such oxidation eliminated as  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . Whether or no intermediate products are formed, is still uncertain; the probability, however, is that there are. The oxidation of sugar is impeded in diabetes.

Where this oxidation, or any of its steps, occurs, is at present a matter of conjecture merely. If, as is usually believed, glucose disappears to a marked extent in the passage of the blood through the lungs, the fact is a strong support of the view that its transformation into  $\text{CO}_2$  and  $\text{H}_2\text{O}$  does not occur as a simple oxidation, as the notion that sugar or any other substance is "burned" in the lung, beyond the small amount required by the nutrition of the organ itself, is scarcely tenable at the present day.

So long as the quantity of glucose in the blood remains at or below the normal percentage, it is not eliminated in the urine in quantities appreciable by the tests usually employed. When, however, the amount of glucose in the blood surpasses this limit from any cause, the urine becomes saccharine, and that to an extent proportional to the increase of glucose in the circulating fluids. The causes which may bring about such an increase are numerous and varied. Many of them are entirely consistent with health, and the mere presence of increased quantities of sugar in the urine is no proof, taken by itself, of the existence of diabetes.

Sugar is detectable by the ordinary tests in the urine under the following circumstances:

*Physiologically*.—(1.) In the urine of pregnant women and during lactation. It appears in the latter stages of gestation and does not disappear entirely until the suppression of the lacteal secretion. (2.) In small quantities in sucking children from eight days to two and one-half months. (3.) In the urine of old persons (seventy to eighty years). (4.) In those whose food contains a large amount of starchy or saccharine material. To this cause is due the apparent prevalence of diabetes in certain localities, as in districts where the different varieties of sugar are produced.

*Pathologically*.—(1.) In abnormally stout persons, especially in old persons and in women at the period of the menopause. The quantity does not exceed 8 to 12 grams per 1,000 c.c. (3.5–5.5 grains per ounce), and disappears when starchy and saccharine food is withheld. This form of glycosuria is liable to develop into true

diabetes when it appears in young persons. (2.) In diseases attended with interference of the respiratory processes—lung diseases, etc. (3.) In diseases where there is interference with the hepatic circulation—hepatic congestion, compression of the portal vein by biliary calculi, cirrhosis, atrophy, fatty degeneration, etc. (4.) In many cerebral and cerebro-spinal disturbances—general paresis, dementia, epilepsy; by puncture of the fourth ventricle. (5.) In intermittent and typhus fevers. (6.) By the action of many poisons—carbon monoxid, arsenic, chloroform, curari; by injection into an artery of ether, ammonia, phosphoric acid, sodium chlorid, amyl nitrite, glycogen. (7.) In true diabetes the elimination of sugar in the urine is constant, unless arrested by suitable regulation of diet, and not temporary, as in the conditions previously mentioned. The quantity of urine is increased, sometimes enormously, and it is of high sp. gr. The elimination of urea is increased absolutely, although the quantity in 1,000 c.c. may be less than that normally existing in that bulk of urine. The quantity of sugar in diabetic urine is sometimes very large; an elimination of 200 grams (6.4 ounces) in twenty-four hours is by no means uncommon; instances in which the amount has reached 400 to 600 grams (12.9–19.3 ounces) are recorded, and one case in which no less than 1,376 grams (45 ounces) were discharged in one day. The elimination is not the same at all hours of the day; during the night less sugar is voided than during the day; the hourly elimination increases after meals, reaching its maximum in 4 hours, after which it diminishes to reach the minimum in 6 to 7 hours, when it may disappear entirely. This variation is more pronounced the more copious the meal. It is obvious from the above, that, in order that quantitative determinations of sugar in urine shall be of clinical value, it is necessary that the determination be made in a sample taken from the mixed urine of twenty-four hours.

**Analytical Characters.**—A saccharine urine is usually abundant in quantity, pale in color, of high sp. gr., covered with a persistent froth on being shaken, and exhales a peculiar odor; when evaporated it leaves a sticky residue. The presence of glucose in urine is indicated by the following tests:

If the urine be albuminous, it is indispensable that the albumen be separated before any of the tests for sugar are applied; this is done by adding one or two drops of dilute acetic acid, or, if the urine be alkaline, just enough acetic acid to turn the reaction to acid, *and no more*, heating over the water-bath until the albumen has separated in flocks, and filtering.

(1.) When examined by the polarimeter (see p. 25) it deviates the plane of polarization to the right.

(2.) When mixed with an equal volume of liquor potassæ and

heated, it turns yellow, and, if sugar be abundant, brown. A molasses-like odor is observable on adding  $\text{HNO}_3$  (Moore's test).

(3.) The urine, rendered faintly blue with indigo solution and faintly alkaline with sodium carbonate, and heated to boiling without agitation, turns violet and then yellow if sugar be present; on agitation the blue color is restored (Mulder-Neubauer test).

(4.) About 1 c.c. of the urine, diluted with twice its bulk of water, is treated with two or three drops of cupric sulphate solution and about 1 c.c. of caustic potassa solution; if sugar be present the bluish precipitate is dissolved on agitation, forming a blue solution. The clear blue fluid, when heated to near boiling, deposits a yellow, orange, or red precipitate of cuprous oxid if sugar be present (Trommer's test). In the application of this test an excess of cupric sulphate is to be avoided, lest the color be masked by the formation of the black cupric oxid. Sometimes no precipitate is formed, but the liquid changes in color from blue to yellow. This occurs in the presence of small quantities of cupric salt and large quantities of sugar, the cuprous oxid being held in solution by the excess of glucose. In this case the test is to be repeated, using a sample of urine more diluted with water. In some instances, also, the reaction is interfered with by excess of normal constituents of the urine, uric acid, creatinin, coloring matter, etc., and instead of a bright precipitate, a muddy deposit is formed. When this occurs the urine is heated with animal charcoal and filtered; the filtrate evaporated to dryness; the residue extracted with alcohol; the alcoholic extract evaporated; the residue redissolved in water, and tested as described above.

(5.) Four or five c.c. of Fehling's solution (see p. 374) are heated in a test-tube to boiling; it should remain unaltered. The urine is then added, and the mixture boiled after each addition of 4-5 drops; if it contain sugar, the mixture turns green, and a yellow or red precipitate of cuprous oxid is formed, usually darker in color than that obtained by Trommer's test. The absence of glucose is not to be inferred until a bulk of urine equal to that of the Fehling's solution used has been added, and the mixture boiled from time to time without the formation of a precipitate. This test is the most convenient and the most reliable for clinical purposes.

(6.) A few c.c. of the urine are mixed in a test-tube with an equal volume of solution of sodium carbonate (1 pt. crystal. carbonate and 3 pts. water), a few granules of bismuth subnitrate are added, and the mixture boiled for some time (until it begins to "bump," if necessary). If sugar be present, the bismuth powder turns brown or black by reduction to elementary bismuth

(Boettger's test). No other normal constituent of the urine reacts with this test; a fallacy is, however, possible from the presence of some compound, which, by giving up sulphur, may cause the formation of the black bismuth sulphid. To guard against this, when an affirmative result has been obtained, another sample of urine is rendered alkaline and boiled with pulverized litharge; the powder should not turn black.

Nylander's test is a mere modification of Boettger's, in which the Bi is used in solution. The test solution is made by dissolving 2.5 parts Bi ( $\text{NO}_3$ )<sub>3</sub> and 4 parts of Rochelle salt in 100 parts of a solution of NaHO of 8% strength. To use the reagent it is mixed with one-tenth its volume of the urine and boiled. In the presence of glucose a black ppt. is formed. The same precautions with regard to sulphur compounds are necessary.

(7.) A solution of sugar, mixed with good yeast and kept at 25° (77° F.) is decomposed into  $\text{CO}_2$  and alcohol. To apply the fermentation-test to urine, take three test-tubes, A, B, and C, place in each some washed (or compressed) yeast, fill A completely with the urine to be tested, and place it in an inverted position, the mouth below the surface of some of the same urine in another vessel (the entrance of air being prevented, during the inversion, by closing the opening of the tube with the finger, or a cork on the end of a wire, until it has been brought below the surface of the urine). Fill B completely with some urine to which glucose has been added, and C with distilled water, and invert them in the same way as A: B in saccharine urine, and C in distilled water. Leave all three tubes in a place where the temperature is about 25° (77° F.) for twelve hours, and then examine them. If gas have collected in B over the surface of the liquid, and none in A, the urine is free from sugar; if gas have collected in both A and B, and not in C, the urine contains sugar; if no gas have collected in B, the yeast is worthless, and if any gas be found in C, the yeast itself has given off  $\text{CO}_2$ . In the last two cases the process must be repeated with a new sample of yeast.

**Quantitative Determination of Glucose.**—(1.) *By the polarimeter.*—The filtered urine is observed by the polariscope (see p. 25) and the mean of half a dozen readings taken as the angle of deviation. From this the percentage of sugar is determined by the formula  $p = \frac{a}{52.85 \times l} \times 100$ , in which  $p$  = the weight, in grams, of glucose in 1 c.c. of urine;  $a$  = the angle of deviation;  $l$  = the length of the tube in decimetres. The same formula may be used for other substances by substituting for 52.85 the value of  $[\alpha]_D$  for that substance. If the urine contain albumen, it must be removed before determining the value of  $a$ .

(2.) *By specific gravity; Robert's method.*—The sp. gr. of the

urine is carefully determined at 25° (77° F.); yeast is then added, and the mixture kept at 25° (77° F.) until fermentation is complete; the sp. gr. is again observed, and will be found to be lower than before. Each degree of diminution represents 0.2196 gram of sugar in 100 c.c. (1 grain per ounce) of urine.

(3.) *By Fehling's solution.*—Of the many formulæ for Fehling's solutions, the one to which we give the preference is that of Dr. Piffard. Two solutions are required:

- |     |  |              |
|-----|--|--------------|
| I.  | Cupric sulphate (pure, crystals).....    | 51.98 grams. |
|     | Water.....                               | 500.0 c.c.   |
| II. | Rochelle salt (pure, crystals) .....     | 259.9 grams. |
|     | Sodic hydrate solution, sp. gr. 1.12 ... | 1000.0 c.c.  |

When required for use, one volume of No. I. is mixed with two volumes of No. II. The copper contained in 20 c.c. of this mixture is precipitated as cuprous oxid by 0.1 gram glucose.

To use the solution, 20 c.c. of the mixed solutions are placed in a flask of 250–300 c.c. capacity, 40 c.c. of distilled water are added, the whole thoroughly mixed and heated to boiling. On the other hand, the urine to be tested is diluted with four times its volume of water if poor in sugar, and with nine times its volume if highly saccharine (the degree of dilution required is, with a little practice, determined by the appearance of the deposit obtained in the qualitative testing); the water and urine are thoroughly mixed and a burette filled with the mixture. A few drops of aqua ammoniæ are added to the Fehling's solution and the diluted urine added, in small portions toward the end, until the blue color is entirely discharged—the contents of the flask being made to boil briskly between each addition from the burette. When the liquid in the flask shows no blue color, when looked through with a white background, the reading of the burette is taken. This reading, divided by five if the urine was diluted with four volumes of water, or by ten if with nine volumes, gives the number of c.c. of urine containing 0.1 gram of glucose; and consequently the elimination of glucose in twenty-four hours, in decigrams, is obtained by dividing the number of c.c. of urine in twenty-four hours by the result obtained above.

*Example.*—20 c.c. Fehling's solution used, and urine diluted with four volumes of water.

Reading of burette:  $36.5 \text{ c.c.} \times \frac{36.5}{5} = 7.3 \text{ c.c.}$  urine contain 0.1 gram glucose. Patient is passing 2.436 c.c. urine in twenty-four hours.  $\frac{2.436}{7.3} = 333.6 \text{ decigr.} = 33.36 \text{ grams glucose in twenty-four hours.}$

The accuracy of the determination may be controlled by filter-

ing off some of the fluid from the flask at the end of the reaction; a portion of the filtrate is acidulated with acetic acid and treated with potassium ferrocyanid solution; if it turn reddish-brown the reduction has not been complete, and the result is affected with a plus error. To another portion of the filtrate a few drops of cupric sulphate solution are added and the mixture boiled: if any precipitation of cuprous oxid be observed, an excess of urine has been added, and the result obtained is less than the true one.

This method, when carefully conducted with accurately prepared and undeteriorated solutions, is the best adapted to clinical uses. The copper solution should be kept in the dark, in a well-closed bottle, and the stopper and neck of the No. II. bottle should be well coated with paraffin.

(4.) *Gravimetric method.*—When more accurate results than are obtainable by Fehling's volumetric process are desired, recourse must be had to a determination of the weight of cuprous oxid obtained by reduction. A small quantity of freshly prepared Fehling's solution is heated to boiling in a small flask: to it is gradually added, with the precautions observed in the volumetric method, a known volume of urine, such that at the end of the reduction there shall remain an excess of unreduced copper salt. The flask is now completely filled with boiling  $H_2O$ , corked, and allowed to cool. The alkaline fluid is separated as rapidly as possible from the precipitated oxid, by decantation and filtration through a small double filter, and the precipitate and flask repeatedly washed with hot  $H_2O$  until the washings are no longer alkaline; a small portion of the precipitate remains adhering to the walls of the flask. The filter and its contents are dried and burned in a weighed porcelain crucible; when this has cooled, the flask is rinsed out with a small quantity of  $HNO_3$ : this is added to the contents of the crucible, evaporated over the water-bath, the crucible slowly heated to redness, cooled, and weighed. The difference between this last weight and that of the crucible + that of the filter-ash, is the weight of cupric oxid, of which 220 parts=100 parts of glucose.

*Lævulose*—*Uncrystallizable sugar*—forms the uncrystallizable portion of the sugar of fruits and of honey, in which it is associated with glucose; it is also produced artificially by the prolonged action of boiling water upon inulin; and as one of the constituents of inverted sugar.

Lævulose is not capable of crystallization, but may be obtained as a thick syrup; very soluble in water, insoluble in absolute alcohol; it is sweeter but less readily fermentable than glucose, which it equals in the readiness with which it reduces cupropotassic solutions. Its prominent physical property, and that to which it owes its name, is its strong left-handed polarization,

$[\alpha]_D = -106^\circ$  at  $15^\circ$  ( $59^\circ$  F.). At  $170^\circ$  ( $338^\circ$  F.) it is converted into the solid, amorphous **lævulosan**,  $C_6H_{10}O_5$ .

**Mannitose**—is obtained by the oxidation of mannite. It is a yellow, uncrystallizable sugar, having many of the characters of glucose, but optically inactive.

**Galactose**—sometimes improperly called lactose—is formed by the action of dilute acids upon lactose (milk-sugar) as glucose is formed from saccharose. It differs from glucose in crystallizing more readily, in being very sparingly soluble in cold alcohol, in its action upon polarized light,  $[\alpha]_D = +83.33$ , and in being oxidized to mucic acid by  $HNO_3$ . The substance called **cerebrose**, obtained by the action of  $H_2SO_4$  on cerebrin and other constituents of nerve-tissue, is identical with galactose.

**Inosite**—*Muscle-sugar*—exists in the liquid of muscular tissue, in the lungs, kidneys, liver, spleen, brain, and blood; pathologically in the urine in Bright's, diabetes, and after the use of drastics in uræmia, and in the contents of hydatid cysts; also in the seeds and leaves of certain plants. What the source and function of inosite in the animal economy may be is still a matter of conjecture.

It forms long, colorless, monoclinic crystals, containing 2 Aq, usually arranged in groups having a cauliflower-like appearance. It effloresces in dry air; has a distinctly sweet taste; is easily soluble in water, difficultly in alcohol; insoluble in absolute alcohol and in ether; it is without action upon polarized light.

The position of inosite in this series is based entirely upon its chemical composition, as it does not possess the other characteristics of the group. It does not enter directly into alcoholic fermentation, although upon contact with putrefying animal matters it produces lactic and butyric acids; when boiled with barium or potassium hydrate, it is not even colored; in the presence of inosite, potash precipitates with cupric sulphate solution, the precipitate being redissolved in an excess of potash; but no reduction takes place upon boiling the blue solution.

The presence of inosite is indicated by the following reactions: *Scherer's*.—Treated with  $HNO_3$ , the solution evaporated to near dryness, and the residue moistened with ammonium hydrate and calcium chlorid, and again evaporated; a rose-pink color is produced. Succeeds only with nearly pure inosite. *Gallois's*.—Mercuric nitrate produces, in solutions of inosite, a yellow precipitate, which, on cautious heating, turns red; the color disappears on cooling, and reappears on heating.

#### Saccharoses, $C_{12}H_{22}O_{11}$ —342.

**Saccharose**—Cane-sugar—Beet-sugar—**Saccharum** (U. S.)—the most important member of the group, exists in many roots, fruits,

and grasses, and is produced from the sugar-cane, *Saccharum officinarum*, sorghum, *Sorghum saccharatum*, beet, *Beta vulgaris*, and sugar-maple, *Acer saccharinum*.

For the extraction of sugar the expressed juice is heated in large pans to about 100 (212° F.); milk of lime is added, which causes the precipitation of albumen, wax, calcic phosphate, etc.; the clear liquid is drawn off, and "delimed" by passing a current of CO<sub>2</sub> through it; the clear liquid is again drawn off and evaporated, during agitation, to the crystallizing-point; the product is drained, leaving what is termed **raw** or **muscovado sugar**, while the liquor which drains off is **molasses**. The sugar so obtained is purified by the process of "refining," which consists essentially in adding to the raw sugar, in solution, albumen in some form, which is then coagulated, filtering first through canvas, afterward through animal charcoal; the clear liquid is evaporated in "vacuum-pans," at a temperature not exceeding 72 (161.6° F.), to the crystallizing-point. The product is allowed to crystallize in earthen moulds; a saturated solution of pure sugar is poured upon the crystalline mass in order to displace the uncrystallizable sugar which still remains, and the loaf is finally dried in an oven. The liquid displaced as above is what is known as **sugar-house syrup**.

Pure sugar should be entirely soluble in water; the solution should not turn brown when warmed with dilute potassium hydrate solution; should not reduce Fehling's solution, and should give no precipitate with ammonium oxalate.

**Beet-sugar** is the same as cane-sugar, except that, as usually met with in commerce, it is lighter, bulk for bulk. **Sugar-candy**, or **rock-candy**, is cane-sugar allowed to crystallize slowly from a concentrated solution without agitation. **Maple-sugar** is a partially refined, but not decolorized variety of cane-sugar.

Saccharose crystallizes in small, white, monoclinic prisms; or, as sugar-candy, in large, yellowish, transparent crystals; sp. gr. 1.606. It is very soluble in water, dissolving in about one-third its weight of cold water, and more abundantly in hot water. It is insoluble in absolute alcohol or ether, and its solubility in water is progressively diminished by the addition of alcohol. Aqueous solutions of cane-sugar are dextrogyrous,  $[\alpha]_D^{20} = +73.8$ .

When saccharose is heated to 160 (320° F.) it fuses, and the liquid, on cooling, solidifies to a yellow, transparent, amorphous mass, known as **barley-sugar**; at a slightly higher temperature, it is decomposed into glucose and levulosan; at a still higher temperature, H<sub>2</sub>O is given off, and the glucose already formed is converted into glucosan; at 210 (410° F.) the evolution of H<sub>2</sub>O is more abundant, and there remains a brown material known as **caramel**, or **burnt sugar**; a tasteless substance, insoluble in strong

alcohol, but soluble in  $H_2O$  or aqueous alcohol, and used to communicate color to spirits; finally, at higher temperatures, methyl hydrid and the two oxids of carbon are given off; a brown oil, acetone, acetic acid, and aldehyde distil over; and a carbonaceous residue remains.

If saccharose be boiled for some time with  $H_2O$ , it is converted into **inverted sugar**, which is a mixture of glucose and lævulose:  $C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$ . With a solution of saccharose the polarization is dextrogyrous, but, after inversion, it becomes lævogyrous, because the left-handed action of the molecule of lævulose produced,  $[\alpha]_D = -106$ , is only partly neutralized by the right-handed action of the glucose,  $[\alpha]_D = +52.85$ . This inversion of cane-sugar is utilized in the testing of samples of sugar. On the other hand, it is to avoid its occurrence, and the consequent loss of sugar, that the vacuum-pan is used in refining—its object being to remove the  $H_2O$  at a low temperature.

Those acids which are not oxidizing agents act upon saccharose in three ways, according to circumstances: (1) if tartaric and other organic acids be heated for some time with saccharose to  $100-120$  ( $212-248$  F.), compounds known as **saccharids**, and having the constitution of ethers, are formed; (2) heated with mineral acids, even dilute, and less rapidly with some organic acids, saccharose is quickly converted into inverted sugar; (3) concentrated acids decompose cane-sugar entirely, more rapidly when heated than in the cold; with  $HCl$ , formic acid and a brown, flocculent material (ulmic acid?) are formed; with  $H_2SO_4$ ,  $SO_2$  and  $H_2O$  are formed, and a voluminous mass of charcoal remains. Oxalic acid, aided by heat, produces  $CO_2$ , formic acid, and a brown substance (humin?).

Oxidizing agents act energetically upon cane-sugar, which is a good reducing agent. With potassium chlorate, sugar forms a mixture which detonates when subjected to shock, and which deflagrates when moistened with  $H_2SO_4$ . Dilute  $HNO_3$ , when heated with saccharose, oxidizes it to saccharic and oxalic acids. Concentrated  $HNO_3$ , alone or mixed with  $H_2SO_4$ , converts it into the explosive **nitro-saccharose**. Potassium permanganate, in acid solution, oxidizes it completely to  $CO_2$  and  $H_2O$ .

Cane-sugar reduces the compounds of  $Ag$ ,  $Hg$ , and  $Au$ , when heated with their solutions; it does not reduce the cupro-potassic solutions in the cold, but effects their reduction when heated with them, to an extent proportional to the amount of excess of alkali present.

When moderately heated with liquor potassæ, cane-sugar does not turn brown, as does glucose; but by long ebullition it is decomposed by the alkalies much less readily than glucose, with formation of acids of the fatty series and oxalic acid.

With the bases, saccharose forms definite compounds called **sucrates** (improperly saccharates, a name belonging to the salts of saccharic acid). With Ca it forms five compounds. Hydrate of calcium dissolves readily in solutions of sugar, with formation of a Ca compound, soluble in  $H_2O$ , containing an excess of sugar. A solution containing 100 parts of sugar in 600 parts of  $H_2O$  dissolves 32 parts of calcic oxid. These solutions have an alkaline taste; are decomposed, with formation of a gelatinous precipitate, when heated, and with deposition of calcium carbonate and regeneration of saccharose, when treated with  $CO_2$ . Quantities of calcium sucrates are frequently introduced into sugars to increase their weight—an adulteration the less readily detected, as the sucrate dissolves with the sugar. Calcium sucrates exist in the **liq. calcis saccharatus (Br.)**.

Yeast causes fermentation of solutions of cane-sugar, but only after its conversion into glucose. Fermentation is also caused by exposing a solution of sugar containing ammonium phosphate to the air.

During the process of digestion, probably in the small intestine, cane-sugar is converted into glucose.

**Lactose—Milk-sugar—Lactine—Saccharum lactis (U. S., Br.)**—has hitherto been found only in the milk of the mammalia. It may be obtained from skim-milk by coagulating the casein with a small quantity of  $H_2SO_4$ , filtering, evaporating, redissolving, decolorizing with animal charcoal, and recrystallizing.

It forms prismatic crystals; sp. gr. 1.53; hard, transparent, faintly sweet, soluble in 6 parts of cold and in 2.5 parts of boiling  $H_2O$ ; soluble in acetic acid; insoluble in alcohol and in ether; its solutions are dextrogyrous  $[\alpha]_D = +59.3$ . The crystals, dried at  $100^\circ$  ( $212^\circ F.$ ), contain 1 Aq, which they lose at  $150^\circ$  ( $302^\circ F.$ ).

Lactose is not altered by contact with air. Heated with dilute mineral or with strong organic acids, it is converted into galactose.  $HNO_3$  oxidizes it to mucic and oxalic acids. A mixture of  $HNO_3$  and  $H_2SO_4$  converts it into an explosive nitro-compound. With organic acids it forms ethers. With soda, potash, and lime it forms compounds similar to those of saccharose, from which lactose may be recovered by neutralization, unless they have been heated to  $100^\circ$  ( $212^\circ F.$ ), at which temperature they are decomposed. It reduces Fehling's solution, and reacts with Trommer's test.

In the presence of yeast, lactose is capable of alcoholic fermentation, which takes place slowly, and, as it appears, without previous transformation of the lactose into either glucose or galactose. On contact with putrefying albuminoids it enters into lactic fermentation.

The average proportion of lactose in different milks is as follows: Cow, 5.5 per cent.; mare, 5.5; ass, 5.8; human, 5.3; sheep,

4.2; goat, 4.0. When taken internally, it is converted into galactose by the pancreatic secretion; when injected into the blood, it does not appear in the urine, which, however, contains glucose.

**Maltose**—a sugar closely resembling glucose in many of its properties, is formed along with dextrin during the conversion of starch into sugar by the action of diastase and of the cryptolytes

FIG. 40.

of the saliva and pancreatic juice. It crystallizes as does glucose, but differs from that sugar in being less soluble in alcohol and in exerting a dextrogyratory power three times as great.

**Amyloses**,  $n(\text{C}_6\text{H}_{10}\text{O}_5)$ — $n162$ .

**Starch**—*Amylum* (U. S.)—the most important member of the group, exists in the roots, stems, and seeds of all plants. It is

prepared from rice, wheat, potatoes, maniot, beans, sago, arrow-root, etc. The comminuted vegetable tissue is steeped for a considerable time in  $H_2O$  rendered faintly alkaline with soda: the softened mass is then rubbed on a sieve under a current of water, which washes out the starch granules: the washings are allowed to deposit the starch, which, after washing by decantation, is dried at a low temperature.

Starch is a white powder, having a peculiar slippery feel, or it appears in short columnar masses. The granules of starch differ in size and appearance according to the kind of plant from which they have been obtained. They are rounded or egg-shaped masses, having at the centre or toward one end a spot, called the hilum, around which are a series of concentric lines more or less well marked. Differences in size, shape, and markings of starch granules are shown in Fig. 40.

Starch is not altered by exposure to air, except that it absorbs moisture. Commercial starch contains 18 per cent. of  $H_2O$ , of which it loses 8 per cent. in vacuo, and the remaining 10 per cent. at  $145^\circ$  ( $293^\circ$  F.). It is insoluble in alcohol, ether and cold water.

If 15 to 20 parts of  $H_2O$  be gradually heated with 1 part of starch, the granules swell at about  $55^\circ$  ( $131^\circ$  F.), and at  $80^\circ$  ( $176^\circ$  F.) they have reached 30 times their original dimensions; their structure is no longer distinguishable, and they form a translucent, gelatinous mass, commonly known as starch-paste. In this state the starch is said to be hydrated, and, if boiled with much  $H_2O$ , and the liquid filtered, a solution of starch passes through, which is opalescent from the suspension in it of undissolved particles. Cold dilute solutions of the alkalies produce the same effects on starch as does hot water. Hydrated starch is dextrogyrous,  $[\alpha]_D = +216^\circ$ . Dry heat causes the granules of starch to swell and burst: at  $200^\circ$  ( $392^\circ$  F.) it is converted into dextrin; at  $230^\circ$  ( $446^\circ$  F.) it forms a brownish-yellow, fused mass, composed principally of pyrodextrin. Hydrated starch is converted into dextrin by heating with  $H_2O$  at  $160^\circ$  ( $320^\circ$  F.), and, if the action be prolonged, the new product is changed to glucose.

The amount of starch contained in food vegetables varies from about 5 per cent. in turnips to 89 per cent. in rice, as will be observed in the table on page 382.

If starch be ground up with dilute  $H_2SO_4$ , after about half an hour the mixture gives only a violet color with I (see below); if now the acid be neutralized with chalk and the filtered liquid evaporated, it yields a white, granular product, which differs from starch in being soluble in  $H_2O$ , especially at  $50^\circ$  ( $122^\circ$  F.), and in having a lower rotary power,  $[\alpha]_D = +211^\circ$ . If the action be prolonged, the value of  $[\alpha]_D$  continues to sink until it reaches  $+73^\circ.7$ , when the product consists of a mixture of dextrin and

glucose. Concentrated  $\text{HNO}_3$  dissolves starch in the cold, forming a nitro-product called **xylodin** or **pyroxam**, which is insoluble in  $\text{H}_2\text{O}$ , soluble in a mixture of alcohol and ether; explosive.  $\text{HCl}$  and oxalic acid convert starch into glucose. When starch is heated under pressure to 120 (248° F.) with stearic or acetic acid, compounds are formed which seem to be ethers, and to indicate that starch is the hydrate of a trivalent, oxygenated radical,  $(\text{C}_6\text{H}_7\text{O}_2)''$ . Potash and soda in dilute solution convert starch into the soluble modification mentioned above.

A dilute solution of I produces a more or less intense blue-violet color with starch, either dry, hydrated, or in solution, the color disappearing on the application of heat, and returning on cooling. If to a solution of starch, blued by I, a solution of a neutral salt be added, there separates a blue, flocculent deposit of the so-called **iodid of starch**. Iodin renders starch soluble in water, and a soluble iodized starch, **Amylum iodatum** (U. S.), is obtained by triturating together 19 pts. starch, 2 pts. water, and 1 pt. iodin, and drying below 40° (104° F.).

Starch has not been found in the animal economy outside of the

alimentary canal, in which, as a prerequisite to its absorption, it must be converted into dextrin and glucose. This change is partially effected by the action of the saliva; more rapidly with hydrated than with dry starch, and more rapidly with the saliva of some animals than that of others; those of man and of the rabbit acting much more quickly than those of the horse and dog. A great part of the starch taken with the food passes into the small intestine unchanged; here, under the influence of a pancreatic cryptolyte, a further transformation into glucose, and of a portion into lactic and butyric acids, takes place.

During the germination of grain, as in the process of malting, a peculiar, nitrogenized substance is produced, which is known as diastase. Under the influence of this body the starch is more or less completely converted into glucose, in very much the same way as the conversion occurs in the body.

This "diastatic" action, whether produced by vegetable or animal processes, does not take place by a simple conversion of starch into glucose, by some such single reaction as that expressed by  $C_6H_{10}O_5 + H_2O = C_6H_{12}O_6$ , but by successive stages in which "soluble starch" is first produced, then several bodies called *dextrins*, then maltose, and finally glucose. (See Dextrin, p. 384.)

*Glycogen* occurs in the liver, the placenta, white blood-corpuscles, pus-cells, young cartilage-cells, in many embryonic tissues, and in muscular tissue. During the activity of muscles the amount of glycogen which they contain is diminished, and that of sugar increased.

Pure glycogen is a snow-white, floury powder; amorphous, tasteless, and odorless; soluble in  $H_2O$ , insoluble in alcohol and ether. In  $H_2O$  it swells up at first, and forms an opalescent solution, which becomes clear on the addition of potash. Its solutions are dextrogyrous to about three times the extent of those of glucose.

Dilute acids, ptyalin, pancreatin, extract of liver-tissue, blood, diastase, and albuminoids convert glycogen into a sugar having all the properties of glucose. Cold  $HNO_3$  converts it into xyloidin; on boiling, into oxalic acid. Its solutions dissolve cupric hydrate, which is, however, not reduced on boiling. Iodin colors glycogen wine-red.

Concerning the method of formation of glycogen in the economy, but little is known with certainty; there is little room for doubting, however, that while the bulk of the glycogen found in the liver results from modification of the carbohydrates, it may be and is produced from the albuminoids as well. The ultimate fate of glycogen is undoubtedly its transformation into sugar under the influence of the many substances existing in the body capable of provoking that change. This transformation is con-

tinuous in the liver during life, and is accomplished through the same series of intermediary changes into dextrins and maltose as in the case of the conversion of starch into sugar, except that possibly the structure of the dextrins may be different.

**Dextrin**—*British gum*—a substance resembling gum arabic in appearance and in many properties, is obtained by one of three methods: (1) by subjecting starch to a dry heat of 175° (347° F.); (2) by heating starch with dilute  $\text{H}_2\text{SO}_4$  to 90° (194° F.) until a drop of the liquid gives only a wine-red color with iodine; neutralizing with chalk, filtering, concentrating, precipitating with alcohol; (3) by the action of diastase (infusion of malt) upon hydrated starch. As soon as the starch is dissolved the liquid must be rapidly heated to boiling to prevent saccharification.

Commercial dextrin is a colorless, or yellowish, amorphous powder, soluble in  $\text{H}_2\text{O}$  in all proportions, forming mucilaginous liquids. When obtained by evaporation of its solution, it forms masses resembling gum arabic in appearance. Its solutions are dextrogyrous, and reduce cupro-potassic solutions under the influence of heat, to amounts varying with the method of formation of the sample. It is colored wine-red by iodine. It is extensively used as a substitute for gum acacia.

By the action of diastase upon starch, four dextrins are produced: 1st, **Erythrodextrin**, which is colored red by iodine, and which is easily attacked by diastase; 2d, **Achroodextrin**  $\alpha$ , not colored by iodine; partially converted into sugar by diastase; rotary power  $[\alpha]_D = +210^\circ$ ; reducing power (glucose=100)=12; 3d, **Achroodextrin**  $\beta$ , not colored by iodine, nor decomposable in 24 hours by diastase; rotary power  $+190^\circ$ ; reducing power=12; 4th, **Achroodextrin**  $\gamma$ , not colored by iodine, nor decomposed by diastase; slowly converted into glucose by dilute  $\text{H}_2\text{SO}_4$ ; rotary power  $=+150^\circ$ ; reducing power=28.

An explanation of this series of transformations has been suggested in the supposition that the molecule of starch consists of  $50(\text{C}_{12}\text{H}_{20}\text{O}_{10})$ ; that this is first converted into soluble starch  $10(\text{C}_{12}\text{H}_{20}\text{O}_{10})$ , and that this is then converted into the different forms of dextrin by a series of hydrations attended by simultaneous formation of maltose, of which the final result might be represented by the equation:

**Cellulose**—*Cellulin*—forms the basis of all vegetable tissues. It exists, almost pure, in the pith of elder and of other plants, in the purer, unsized papers, in cotton, and in the silky appendages of certain seeds. Cotton, freed from extraneous matter by boil-

ing with potash, and afterward with dilute  $\text{HCl}$ , yields pure cellulose, in which form it is now met with in commerce under the name "absorbent cotton."

It is a white material, having the shape of the vegetable structure from which it was obtained; insoluble in the usual neutral solvents, but soluble in the deep-blue liquid obtained by dissolving copper in ammonia in contact with air.

Vegetable parchment, or parchment paper, is a tough material, possessing many of the valuable properties of parchment, made by immersing unsized paper for an instant in moderately strong  $\text{H}_2\text{SO}_4$ , washing thoroughly, and drying.

**Nitro-cellulose.**—By the action of  $\text{HNO}_3$  upon cellulose (cotton) three different products of substitution may be obtained: **mono-nitro-cellulose**, soluble in acetic acid, insoluble in a mixture of ether and alcohol; **dinitro-cellulose**, insoluble in acetic acid, soluble in a mixture of ether and alcohol; **trinitro-cellulose**, soluble in both the above solvents. **Gun-cotton** or **pyroxylin** is composed of varying proportions of these three derivatives. When gun-cotton is required as an explosive agent, the process is so managed that the product shall contain the greatest possible proportion of trinitro-cellulose, the most readily inflammable of the three. When required for the preparation of collodion, for use in medicine or in photography, dinitro-cellulose is the most valuable. To obtain this, a mixture is made of equal weights of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (of each about 5 times the weight of the cotton to be treated); in this the cotton is immersed and well stirred for about three minutes, after which it is well stirred in a large vessel of water, washed with fresh portions of water until the washings are no longer precipitated by barium chlorid, and dried. **Collodion** is a solution of dinitro-cellulose in a mixture of three volumes of ether and one volume of alcohol. **Celluloid** is gun-cotton and camphor compacted under pressure.

**Lignin** is an isomere of cellulose, which constitutes the greater part of the "incrusting substance" of wood.

**Gums**—are substances of unknown constitution, existing in plants; amorphous; soluble in water, insoluble in alcohol; converted into glucose by boiling with dilute  $\text{H}_2\text{SO}_4$ .

**Lichenin** is obtained from various lichens by extraction with boiling water, forming a jelly on cooling; it is oxidized to oxalic acid by  $\text{HNO}_3$ ; is colored yellow by iodine; and is precipitated from its solutions by alcohol.

**Arabin** is the soluble portion of gum arabic and gum senegal—**Acacia** (**U. S.**). To separate it, gum arabic is dissolved in water acidulated with  $\text{HCl}$ , and precipitated by alcohol. It is a white, amorphous, tasteless substance, which is not colored by iodine; is oxidized by  $\text{HNO}_3$  to mucic and saccharic acids; is converted by

$\text{H}_2\text{SO}_4$  into a non-fermentable sugar, arabinose; and has the composition,  $\text{C}_{12}\text{H}_{20}\text{O}_{10} + 1\text{Aq}$ .

**Bassorin** constitutes the greater part of gum tragacanth; it is insoluble in water, but swells up to a jelly in that fluid.

**Cerasin** is an insoluble gum exuded by cherry- and plum-trees; water acts upon it as upon bassorin.

## CYCLIC HYDROCARBONS AND THEIR DERIVATIVES.

## AROMATIC SUBSTANCES.

It is among the compounds of this series that the most important products of synthetic chemistry are to be found; and it is in dealing with them that theoretic chemistry has received the widest applications.

Although many of these bodies occur in nature, by far the greater number, including all the hydrocarbons except the members of the paraffene and terebenthene groups, are artificial products.

Although the members of the acyclic and of the cyclic families are not readily converted into each other, acyclic compounds are frequently grafted upon cyclic, and cyclic compounds are frequently decomposed with formation of acyclic derivatives, but in the latter case cyclic derivatives are simultaneously produced.

Among the instances of conversion of acyclic into cyclic compounds is one of interest as bearing upon the constitution and relationships of the cyclic hydrocarbons, and as showing their pyrogenic origin.

We have seen that one of the constituents of coal-gas is acetylene,  $\text{H}-\text{C}\equiv\text{C}-\text{H}$ . The central figure of the cyclic compounds is benzene,  $\text{C}_6\text{H}_6$ , which is obtained principally from gas-tar: and whose molecule may clearly be considered as produced by the union of three molecules of acetylene,  $3\text{C}_2\text{H}_2 = \text{C}_6\text{H}_6$ . If we represent three molecules of acetylene by 1, 2, 3, A or B, Fig. 41 (the larger circles representing the carbon, and the smaller the hydrogen atoms), it is easy to conceive that by the action of heat one of the three bonds uniting the two C atoms may be loosened, and that the neighboring C atoms will then attach themselves to each other, exchanging the valences thus liberated, and produce a molecule of benzene. The arrangement A produces the "pris-

FIG. 41.

matic formula," the arrangement B the "hexagonal formula" of benzene, usually represented in writing thus :

It is hardly necessary to mention that such formulæ are merely schematic, intending to represent the relations of the atoms, but not intending to convey any idea of the shape of the molecule.

Although the hexagonal expression is more frequently met with than the prismatic, and is in some respects more manageable, the prismatic in some cases better explains the structure of the molecule.

Although substances are known which contain a cyclic nucleus made up of a number of C atoms less than six, all cyclic compounds may be considered as derivable from benzene, and all contain the benzene nucleus or benzene ring,  $C_6H_6$ , more or less modified by addition, by substitution or by subtraction.

Some of the benzene derivatives are produced by simple grafting of lateral, open-chain groups upon a benzene nucleus, as shown at A, others by the union of two or more benzene rings with each other as shown at B :

and all the molecules so formed are capable of deeper modification by further substitution of atoms or groups for the remaining H atoms.

The prismatic formula given above may also be opened out, and the molecule thus gain two, four, or six valences, thus :

Condensation and substitution may also occur in the benzene ring itself, giving rise to compounds containing modified nuclei, such as :

The benzenic hydrocarbons (and their derivatives) are divided into groups according to the number of benzene nuclei, more or less modified, which they contain. Thus we have :

Monobenzenic hydrocarbons—containing one benzene nucleus.

Dibenzenic hydrocarbons—containing two benzene nuclei.

Tribenzenic hydrocarbons—containing three benzene nuclei, etc.

## MONOBENZENIC HYDROCARBONS.

### SERIES $C_nH_{2n-6}$

The hydrocarbons of this series are the starting-points from which the major part of the cyclic compounds are obtainable or derivable. Those at present known are :

Benzene.....	$C_6H_6$ .....	boils at $80^\circ.4$ ( $176^\circ.7$ F.)
Toluene.....	$C_7H_8$ .....	boils at $110^\circ.3$ ( $230^\circ.5$ F.)
Xylene.....	$C_8H_{10}$ .....	boils at $142^\circ.0$ ( $287^\circ.6$ F.)
Cumene.....	$C_9H_{12}$ .....	boils at $151^\circ.4$ ( $304^\circ.5$ F.)
Cymene....	$C_{10}H_{14}$ .....	boils at $175^\circ.0$ ( $347^\circ.0$ F.)
Laurene.....	$C_{11}H_{16}$ .....	boils at $188^\circ.0$ ( $370^\circ.4$ F.)

The terms above benzene may be obtained by a general reaction, by treating a mixture of monobrombenzene, ether and the bromid or iodid of the corresponding alcoholic radical with sodium in excess :

The reaction is violent and small quantities only (30-40 grams) can be operated on.

**Benzene**—*Benzol*—*Phenyl hydrid*— $C_6H_6$ —78—(not to be confounded with the commercial *benzine*, a mixture of hydrocarbons of the series  $C_nH_{2n+2}$ , obtained from petroleum) does not exist in nature, but is produced in a number of reactions. It is obtained by one of two methods, according as it is required chemically pure or mixed with other substances.

To obtain it pure, recourse must be had to the decomposition of one of its derivatives, benzoic acid; this substance is intimately mixed with 3 pts. slacked lime, and the mixture heated to dull redness in an earthenware retort, connected with a well-cooled receiver; the upper layer of distilled liquid is separated, shaken with potassium hydrate solution, again separated, dried by contact with fused calcium chlorid, and redistilled over the water-bath.

For use in the arts, and for most chemical purposes, benzene is obtained from coal- or gas-tar, an exceedingly complex mixture, containing some forty or fifty substances, among which are :

## HYDROCARBONS.

Benzene.	Cymene.	Anthracene.
Toluene.	Naphthalene.	Retene.
Xylene.	Acenaphthalene.	Chrysene.
Cumene.	Fluorene.	Pyrene.

## ACIDS.

Carbolic.	Phlorylic.	Oxyphenic.
Cresylic.	Rosolic.	

## BASES.

Pyridin.	Collidin.	Aceridin.
Anilin.	Leucolin.	Coridin.
Picolin.	Iridolin.	Rubidin.
Lutidin.	Cryptidin.	Viridin.

By a primary distillation of coal-tar the most volatile constituents, including benzene, are separated as **light oil**; this is washed, first with  $\text{H}_2\text{SO}_4$ , and then with caustic soda, and afterward redistilled; that portion being collected which passes between 80° and 85° (176°–185° F.). This is the commercial benzene, a product still contaminated with the higher homologues of the same series, from which it is almost impossible to separate it, but whose presence is necessary for the principal use to which benzene is put—the manufacture of anilin dyes.

Benzene is a colorless, mobile liquid, having, when pure, an agreeable odor; sp. gr. 0.86 at 15° (59° F.); crystallizing at +4.5° (40.1° F.); boiling at 80.5° (176.9° F.); very sparingly soluble in water, soluble in alcohol, ether, and acetone. It dissolves I, S, P, resins, caoutchouc, gutta-percha, and almost all the alkaloids. It is inflammable, and burns with a luminous, smoky flame.

Benzene unites with Cl or Br to form products of addition, or of substitution; the corresponding iodine compounds can only be obtained by indirect methods. Sulphuric acid combines with benzene to form a neutral substance, **sulpho-benzid**, when the anhydrous acid is used, and **phenyl-sulphurous acid** with the ordinary  $\text{H}_2\text{SO}_4$ .

If fuming  $\text{HNO}_3$  of sp. gr. 1.52 be slowly added to benzene, a

reddish liquid is formed; from which, on the addition of  $H_2O$  a reddish-yellow oil separates, and is purified by washing with  $H_2O$  and with sodium carbonate solution, drying and rectifying. This oily material is mononitro-benzene (see p. 411). If benzene be boiled with fuming  $HNO_3$ , or if it be dropped into a mixture of  $HNO_3$  and  $H_2SO_4$ , so long as the fluids mix, a crystalline product, dinitro-benzene, is formed.

The superior homologues of benzene include many isomeres. As they are derivable from benzene by substitution of a hydrocarbon radical or radicals  $C_nH_{2n+1}$  for one or more atoms of hydrogen, the following isomeres may exist:

The number of isomeres among the higher terms of the series is further increased by the occurrence of increasing numbers of isomeres among the substituted radicals themselves, as  $CH_2-CH_2-CH_3$  and  $CH \begin{smallmatrix} \diagup CH_3 \\ \diagdown CH_3 \end{smallmatrix}$ , etc. Further, when the number of substituted groups is greater than one, different substances are produced by the substitution of the same groups in positions bearing different relations to each other in the benzene nucleus.

In the case of benzene itself there exist products of substitution containing 1, 2, 3, 4, 5, and 6 groups  $CH_3, C_2H_5$ , etc. (or other radicals or univalent atoms), or combinations of two or three of those radicals or elements. In the case of the unsubstituted derivatives,  $C_6H_5, CH_3; C_6H_5, C_2H_5$ , etc., but one of each exists. Of the bisubstituted, trisubstituted, and quadrisubstituted derivatives three of each are known.

From the existence of but one unsubstituted derivative it is obvious that it is immaterial in which of the  $CH$  groups this substitution occurs, and hence these six groups are equal to each other in value. The existence of isomeres of the higher products of substitution depends upon differences in the relative positions of the substituted radicals or atoms to each other, their orientation, as it is called, and not to their absolute positions.

If we represent the molecule of benzene by a hexagon, leaving out the  $H$  atoms for the sake of brevity, we may start from any angle and number the angles, or positions, from 1 to 6:

In such a hexagon there are three possible positions with relation to each other, in which two atoms or radicals may be placed.

They may be *consecutive*, *i.e.*, occupying two adjoining positions, as 1—2, 2—3, 3—4, 4—5, 5—6, or 6—1; as for instance in 1, in which x may be a radical  $C_nH_{2n+1}$ , a univalent atom, or any

1.

2.

3.

univalent radical. Or the positions may be *unsymmetrical*, 1—3, 2—4, 3—5, 4—6, 5—1, as in 2. Or the substitution may be *symmetrical*, as in 3, occupying the diagonal positions 1—4, 2—5, 3—6.

In the case of trisubstituted derivatives in which the substituted radical or element is the same there may also be three positions, thus :

4.

5.

6.

either *consecutive* as in 4; *unsymmetrical* as in 5; or *symmetrical* as in 6.

The three series of bi- and tri-substituted derivatives of benzene, whether the substitution be of a halogen or of any univalent element or radical, are designated by the prefixes *ortho*, *meta*, and *para*. Thus, in the figures above :

Nos. 1 and 4 = 1—2 = *Ortho*—benzene.

Nos. 2 and 5 = 1—3 = *Meta*—benzene.

Nos. 3 and 6 = 1—4 = *Para*—benzene.

The distinction between the three groups is best made by the relations between the bi- and tri-substituted derivatives. The consecutive or *ortho* bisubstituted derivatives can produce by further substitution two tri-derivatives, one consecutive, the other unsymmetrical; the unsymmetrical, or *meta*, can produce three trisubstituted derivatives; and the symmetrical, or *para*, can produce but one trisubstituted derivative, an unsymmetrical.

In expressing the constitution of substituted derivatives it is customary either to use the prefixes *ortho*, *para*, and *meta*, as explained above, or to designate the substance by the numerical positions of the substituted atoms or radicals, considering the substituted atom or group in the parent mono-substituted derivative as always occupying the position 1.

When, in a trisubstituted derivative, the substituted radicals or atoms are not the same in kind, the number of possible isomeres is further increased. Thus, there are six possible chloro-dibromobenzenes:

of which 1 and 2 are derivable from *orthobibromobenzene*, 3, 4, and 5 from *metabibromobenzene*, and 6 from *parabibromobenzene*. If, in place of two elements or radicals, we have three, the number of trisubstituted derivatives is increased to ten.

The naming of such polysubstituted derivatives presents many difficulties. Adherence to the principle that the name of a compound shall indicate its constitution, involves the construction of names which are frequently of unwieldy length. It is usual to consider the characterizing group as occupying the position 1 in the hexagon, and to prefix the term *ortho* to the name of that

radical or atom occupying one of the ortho-positions 2 and 6 with relation to the characterizing group; **meta** to that occupying one of the meta-positions 3 and 5; and **para** to that occupying the para-position 4.

Thus the substance having the constitution indicated by the formula 1 is designated by the name **orthonitroparabromo-phe-**

**nol.** But even this is not always sufficiently definite, for to each of the substances 2 and 3, although differing in characters, the name **orthonitrometabromo-phenol** applies. It has been suggested, to avoid this difficulty, that the prefix **allortho** be used to designate the second ortho-position 6, and the prefix **allmeta** to designate the second meta-position 5.

The name of No. 3 would thus become **metabromoallorthonitro-phenol**.

When formulæ are used, all confusion may be readily avoided, even in the most complex substances, by the use of the numeral corresponding to the position in the benzene chain, enclosed in brackets. Thus, the formulæ of 2 and 3 above may be written :

In the case of the tetrasubstituted derivatives there are also three possible positions : **consecutive**, 1, 2, 3, 4; **symmetrical**, 1, 3, 4, 6, and **unsymmetrical**, 1, 3, 4, 5.

In these hydrocarbons and in other derivatives of benzene the six atoms of carbon belonging to benzene constitute what is known as the **benzene nucleus**, **benzene ring**, or the **principal chain**; while the substituted groups are designated as the **lateral chains**.

**Toluene—Toluol—Methyl-benzene—C<sub>6</sub>H<sub>5</sub>, CH<sub>3</sub>—92—**exists in the products of distillation of wood, coal, etc., and as one of the constituents of commercial benzene. It has been formed synthetically by acting upon a mixture of monobromo-benzene and methyl iodid with sodium.

It is a colorless liquid, having a peculiar odor, differing somewhat from that of benzene; boils at 110.3 (230.5 F.); does not

solidify at  $-20^{\circ}$  ( $-4^{\circ}$  F.); sp. gr. 0.872 at  $15^{\circ}$  ( $59^{\circ}$  F.); almost insoluble in water, soluble in alcohol, ether, carbon disulphid. It burns with a bright, but very smoky flame. It yields a number of derivatives similar to those of benzene, among which may be mentioned *nitro-toluene* and *toluidin*, the homologues of nitrobenzene and anilin, which accompany those substances in the commercial products; *cresylol*, the superior homologue of carbolic acid, and *benzylic alcohol*.

**Xylenes—Xylols— $C_6H_{10}$ .**—Four isomeres are possible and are known: ethyl-benzene,  $C_6H_5.C_2H_5$ —and ortho- (1—2), meta- (1—3), and para- (1—4), dimethyl-benzenes,  $C_6H_4(CH_3)_2$ . Ethylbenzene is a colorless oil, boiling at  $134^{\circ}$  ( $273.2^{\circ}$  F.), obtained by fractional distillation of animal oil. The three dimethyl benzenes exist in coal-tar and in the commercial xylene, which boils at  $139^{\circ}$  ( $282.2^{\circ}$  F.), 70% consisting of metaxylene, and paraxylene being present in very small amount.

### HALOID DERIVATIVES.

By the substitution of atoms of Cl, Br and I for the hydrogen of the principal and lateral chains in benzene and its superior homologues, a great number of substances are obtained, many of them forming isomeric groups.

The chlorin derivatives of benzene are :

**Monochloro-benzene— $C_6H_5Cl$** —liquid; boils at  $132^{\circ}$  ( $269.6^{\circ}$  F.); sp. gr. 1.128 at  $0^{\circ}$ ; obtained by the action of Cl upon  $C_6H_6$  in the cold, in the presence of a little I.

**Orthodichloro-benzene—1—2**—liquid; boils at  $179^{\circ}$  ( $354.2^{\circ}$  F.); sp. gr. 1.328 at  $0^{\circ}$ ; obtained by the action of Cl on  $C_6H_6$ .

**Metadichloro-benzene—1—3**—liquid; boils at  $172^{\circ}$  ( $341.6^{\circ}$  F.); sp. gr. 1.307 at  $0^{\circ}$ ; obtainable indirectly.

**Paradichloro-benzene—1—4**—crystalline; fuses at  $56^{\circ}.4$  ( $133.5^{\circ}$  F.); boils at  $170^{\circ}$  ( $343.4^{\circ}$  F.); is the principal product of the action of Cl on  $C_6H_6$  in presence of I.

**Metatrichloro-benzene—1—2—4**—crystals; fuses at  $17^{\circ}$  ( $62.6^{\circ}$  F.); boils at  $213^{\circ}$  ( $415.4^{\circ}$  F.).

**Paratrichloro-benzene—1—3—5**—crystals; fuses at  $63^{\circ}.4$  ( $146.1^{\circ}$  F.); boils at  $208^{\circ}$  ( $406.4^{\circ}$  F.).

**Tetrachloro-benzene—1—2—3—5**—crystals; fuses at  $50^{\circ}$  ( $122^{\circ}$  F.); boils at  $246^{\circ}$  ( $474.8^{\circ}$  F.).

**Tetrachloro-benzene—1—2—4—5**—crystals; fuses at  $137^{\circ}$  ( $278.6^{\circ}$  F.); boils between  $243^{\circ}$ — $246^{\circ}$  ( $469.4$ — $474.8^{\circ}$  F.).

**Benzoyl chlorid— $C_6H_5CH_2Cl$** —is an example of the substitution of a halogen in the lateral chain of a superior homologue of benzene. It is obtained by the action of chlorin upon boiling

toluene; or of  $\text{PCl}_5$  on benzoic alcohol. It is a colorless liquid, boils at  $176^\circ$  ( $348.8^\circ \text{F.}$ ), and gives off pungent vapors which excite the lachrymal secretion. It is readily oxidized to benzoic aldehyde or benzoic acid, and serves for the introduction of the radical benzoyl,  $\text{C}_6\text{H}_5\text{CH}_2$  into other molecules.

## PHENOLS.

The hydrocarbons of the benzene series, unlike those previously considered, form two distinct kinds of hydrates, differing from each other materially in their properties. The terms of one of these series exhibit all the functions of the alcohols, and are known as **aromatic alcohols**. The terms of the other series differ in function from any substance thus far considered, and are known as **phenols**. The difference between them and the aromatic alcohols is due to the fact that in the phenols the OH is directly attached to a C atom, while in the alcohols it forms part of the group of atoms  $\text{CH}_2\text{OH}$ , characteristic of the alcohols:

The phenols differ from the alcohols in not furnishing by oxidation corresponding aldehydes and acids; in not dividing into water and hydrocarbon under the influence of dehydrating agents; in not reacting with acids to form ethers; in combining to form directly products of substitution with Cl and Br; and in forming with metallic elements compounds more stable than similar compounds of the true alcohols. In short, the phenols appear to have, besides an alcoholic function, more or less of the function of acids.

**Phenol—Phenyl hydrate—Phenic acid—Carbolic acid—Acidum carbolicum (U. S., Br.)— $\text{C}_6\text{H}_5\text{OH}$ —94—**exists in considerable quantity in coal- and wood-tar, and in small quantity in castoreum, and possibly in urine.

It is formed: (1) by fusing sodium phenylsulphid with an excess of alkali; (2) by heating phenyl iodid with potassium hydrate to  $320^\circ$  ( $608^\circ \text{F.}$ ); (3) by heating together salicylic acid and

quicklime; (4) by total synthesis from acetylene; (5) by dry distillation of benzoin.

The source from which it is obtained is that portion of the product of distillation of coal-tar which passes over between 150° and 200° (302°–392° F.). This is treated with a saturated solution of potash, containing undissolved alkali; a solid phenate is formed, which is dissolved in hot  $H_2O$ ; the liquid is allowed to separate into two layers, the lower of which is drawn off and neutralized with  $HCl$ ; the phenol rises to the surface, is separated, washed with water, dried over calcium chlorid, redistilled, crystallized at  $-10^\circ$  (14° F.), and the crystals drained. A "synthetic phenol," prepared by a secret process, is now obtainable, and seems to be more nearly pure than the "natural" product.

Pure phenol crystallizes in long, colorless, prismatic needles, fusible at  $40^\circ$ – $41^\circ$  (104°–105°.8 F.), boiling at  $181^\circ.5$  (258°.7 F.). It has a peculiar, well-known odor, and an acrid, burning taste; very sparingly soluble in water, readily soluble in alcohol and in ether; sp. gr. 1.065 at 18° (64°.4 F.); neutral in reaction. On contact with the skin or with mucous surfaces, it produces a white stain; it coagulates albuminoids, and is a powerful antiseptic.

It may be distilled without decomposition. It absorbs  $H_2O$  from damp air to form a hydrate, which crystallizes in six-sided prisms, fusible at  $16^\circ$  (60°.8 F.). Its vapor is reduced to benzene when heated with  $Zn$ . It combines with  $H_2SO_4$  to form phenylsulphuric acids. It forms trinitrophenic acid (*q.v.*) with  $HNO_3$  of 36° B. When heated with  $H_2SO_4$  and oxalic acid it forms rosolic acid or corallin, which is a mixture from which the pigments aurin, peonin, azulin, and phenicin are obtained.

**Analytical Characters.**—(1.) Its peculiar odor. (2.) Mix with one-quarter volume of  $NH_4HO$ ; add two drops sodium hypochlorite solution, and warm; a blue or green color. Add  $HCl$  to acid reaction; turns red. (3.) Add two drops of liquid to a little  $HCl$ , add one drop  $HNO_3$ ; a purple red color. (4.) Boil with  $HNO_3$  as long as red fumes are given off. Neutralize with  $KHO$ ; a yellow, crystalline precipitate. (5.) With  $FeSO_4$  solution; a lilac color. (6.) Float the liquid on  $H_2SO_4$ , add powdered  $KNO_3$ ; violet color. (7.) With excess of  $Br$  water; a yellowish-white precipitate.

**Toxicology.**—When taken internally, phenol is an active poison, and one whose use by suicides has become quite common. When it has been taken the mouth is whitened by its caustic action, and there is a marked odor of carbolic acid in the breath. It is eliminated by the urine, partly unchanged, and partly in the form of colored derivatives, which color the urine greenish, brownish, or even black. The treatment consists in the administration of albumen (white of egg) and of emetics.

To detect phenol in the urine, that liquor must not be distilled with  $\text{H}_2\text{SO}_4$ , as sometimes recommended, as it contains normally substances which by such treatment yield carbolic acid. The best method consists in adding an excess of bromin water to about 500 c.c. of the urine; on standing some hours, a yellowish precipitate collects at the bottom of the vessel; this is removed, washed, and treated with sodium amalgam, when the characteristic odor of phenol is developed. From other parts of the body, phenol may be recovered by acidulating with tartaric acid; distilling; extracting the distillate by shaking with ether; evaporating the ethereal solution; extracting the residue with a small quantity of water, and applying to this solution the tests described above.

**Phenates.**—*Carbolates.*—The hydrogen of the oxhydryl group of phenol is replaceable by certain metals and by alcoholic radicals to form phenates. When phenol and KHO are heated together, potassium phenate,  $\text{C}_6\text{H}_5\text{OK}$ , is formed. This, when treated in alcoholic solution with  $\text{HgCl}_2$ , produces mercuric phenate,  $(\text{C}_6\text{H}_5\text{O})_2\text{Hg}$ , a yellow, crystalline solid which has been used in medicine.

The phenylic ethers may be obtained by heating potassium phenate with the iodid of the alcoholic radical.

**Methyl phenate**—**Anisol**— $\text{C}_6\text{H}_5\text{OCH}_3$ —is a colorless, thin liquid, boils at  $152^\circ$  ( $305.6^\circ\text{F.}$ ) without decomposition. Sulphuric acid dissolves it, with formation of methyl-phenol sulphonic acid.

**Ethyl phenate**—**Phenetol**— $\text{C}_6\text{H}_5\text{OC}_2\text{H}_5$ —is a colorless liquid, boils at  $172^\circ$  ( $341.6^\circ\text{F.}$ ), having an aromatic odor.

Anisol and phenetol serve as the starting-points for the production of the anisidins and phenthidins (q.v.).

**Cresols**—**Cresylols**—**Cresylic acids**—**Benzylic or cresylic phenols**— $\text{C}_6\text{H}_4\begin{smallmatrix} \text{CH}_3 \\ \text{OH} \end{smallmatrix}$ —108.—Of the three possible compounds, two, the para and ortho, accompany phenol in coal-tar, from which they may be separated by fractional distillation. They are more readily obtained pure from toluene.

**Ortho-cresol** (1—2) is a crystalline solid, fusible at  $31^\circ$ — $31.5^\circ$  ( $87.8^\circ$ — $88.7^\circ\text{F.}$ ), which assumes a blue color with ferric chlorid.

**Metacresol** (1—3) is obtainable by the action of  $\text{P}_2\text{O}_5$  on thymol. It is a colorless liquid, whose odor resembles that of phenol, boils at  $201^\circ$  ( $393.8^\circ\text{F.}$ ), does not solidify at  $-75^\circ$  ( $-103^\circ\text{F.}$ ).

**Paracresol** (1—4) is a crystalline solid, fusible at  $36^\circ$  ( $96.8^\circ\text{F.}$ ), boiling at  $198^\circ$  ( $388.4^\circ\text{F.}$ ), having a phenol-like odor; colored blue by ferric chlorid.

**Creasote**—**Creasotum** (**U. S.**)—is a complex mixture containing phenol, cresol, creasol,  $\text{C}_8\text{H}_{10}\text{O}_2$ , guaiacol,  $\text{C}_7\text{H}_8\text{O}_2$  (see pyrocatechin), and other substances, obtained from wood-tar, and

formerly extensively used as an antiseptic. It is an oily liquid, colorless when freshly prepared, but becoming brownish on exposure to light; it has a burning taste and a strong, peculiar odor; it boils at  $203^{\circ}$  ( $397.4^{\circ}$  F.), and does not solidify at  $-27^{\circ}$  ( $-16.6^{\circ}$  F.).

Crude phenol is often substituted for creasote; the two substances may be distinguished by the following characters: Phenol gives a brown color with ferric chlorid and alcohol, while creasote gives a green color; phenol dissolves in glycerin, in which creasote is insoluble; phenol precipitates nitro-cellulose from collodion, while creasote does not.

**Xenols—Xylenols.**—Theoretically there are six possible xenols which are dimethyl phenols,  $C_6H_4(CH_3)_2OH$ ; of these, four have been thus far obtained by the general methods of obtaining the phenols. There are also three possible xenols which are ethyl phenols,  $C_6H_4(C_2H_5)OH$ .

**Thymol—Methyl-parapropyl-metaphenol—*Cymylic phenol***— $C_6H_4(CH_3)C_3H_7OH$ —150—exists, accompanying cymene and thymene,  $C_{10}H_{16}$ , in essence of thyme, from which it is obtained. The essence contains about one-half its weight of thymol, which is separated by agitation with a concentrated solution of caustic soda; separation of the alkaline liquid, which is diluted and neutralized with HCl; thymol separates and is purified by rectification at  $230^{\circ}$  ( $446^{\circ}$  F.).

It crystallizes in large, transparent, rhombohedral tables; has a peppery taste, and an agreeable, aromatic odor; it fuses at  $44^{\circ}$  ( $111.2^{\circ}$  F.), and boils at  $230^{\circ}$  ( $446^{\circ}$  F.); is sparingly soluble in water, very soluble in alcohol and ether. With the alkalies it forms definite compounds, which are very soluble in water. Its reactions are very similar to those of phenol.

Thymol is an excellent disinfecting and antiseptic agent, possessing the advantage over phenol of having itself a pleasant odor.

**Carvacrol—Methyl-parapropyl-orthophenol**—an isomere of thymol, whose constitution differs only in the position of the oxhydril group, is obtained by the action of iodine upon camphor; by the action of potash in fusion upon cymene sulphonic acid,  $C_{10}H_{13}SO_3H$ ; or by a transposition of the atoms of another isomere, **carvol**, which exists in caraway oil. It is an oil, boiling at  $233^{\circ}$ – $235^{\circ}$  ( $451.4$ – $455^{\circ}$  F.). Heated with  $P_2O_5$ , it yields orthocresol.

## SUBSTITUTED PHENOLS.

We have seen above (p. 391) how three bi- and tri-substituted derivatives are derivable from benzene. Phenol is a unsubstituted derivative of the same substance and hence still contains

five H atoms which may be replaced by other elements or radicals, to produce di- or tri- or poly-substituted derivatives of benzene, which will be ortho, meta or para, etc., according to the relations of the introduced groups to the OH, already existing in phenol, or to the  $C_nH_{2n+1}$  and OH groups in its superior homologues.

**Chlorophenols.**—The three monochlorinated compounds are obtainable from the corresponding chloranilins. **Orthochlorophenol** (1—2) is a colorless liquid, boils at  $175-176$  ( $347-348$  .8 F.), converted into pyrocatechin by KHO. **Metachlorophenol** (1—3) is a liquid, boiling at  $214$  ( $417$  .2 F.). KHO converts it into resorcin. **Parachlorophenol** (1—4) is a crystalline solid, fusible at  $37$  ( $98$  .6 F.), converted into hydroquinone by fusion with KHO. Di-, tri-, and penta-chlorophenols are also known.

**Bromophenols** correspond in method of formation and properties with the Cl derivatives.

**Iodophenols** are formed by the action of iodine and KS upon phenol in the presence of excess of alkali, or from the corresponding amidophenols. Like the chlorine and bromine derivatives, they yield the corresponding diphenol by the action of KHO in fusion. A tri-iodophenol, formed by the action of solution of I in KS upon an alkaline solution of phenol, has been proposed as a substitute for iodoform under the name **annidalin**.

**Nitro-phenols**—**Mononitro-phenols**— $C_6H_4(NO_2)OH$ —(1—2), (1—3) and (1—4) are formed by the action of  $HNO_3$  on  $C_6H_5OH$ . The **ortho** compound (1—2) crystallizes in large yellow needles, sparingly soluble, and capable of distillation with steam. The **meta** and **para** compounds are both colorless, non-volatile, crystalline bodies. Two **dinitro-phenols**,  $C_6H_3OH(NO_2)_{2(2-4)}$  and  $C_6H_3OH(NO_2)_{2(2-6)}$ , are obtained by the action of strong nitric acid on phenol, or on ortho- or para-mononitro phenol. They are both solid, crystalline substances, converted by further nitration into picric acid.

**Trinitro-phenols**— $C_6H_2(NO_2)_3OH$ .—Two are known: (1.) **Picric acid**—**Carbazotic acid**—**Trinitro-phenic acid**— $(NO_2)_3$  in 2—4—6. It is formed by nitrification of phenol, or of 1—2—4 or 1—2—6 dinitro-phenols, and also by the action of  $HNO_3$  on indigo, silk, wool, resins, etc. It crystallizes in brilliant, yellow, rectangular plates, or in six-sided prisms; it is odorless, and has an intensely bitter taste, whence its name (from *πικρός* = bitter); it is acid in reaction; sparingly soluble in water, very soluble in alcohol, ether, and benzene; it fuses at  $122.5$  ( $252$  .5 F.), and may, if heated with caution, be sublimed unchanged; but, if heated suddenly or in quantity, it explodes with violence. It behaves as a monobasic acid, forming salts, which are for the most part soluble, yellow, crystalline, and decomposed with explosion when heated.

Picric acid is valuable as a dye-stuff, coloring silk and wool

yellow; as a staining medium in histological investigations; and as a reagent for the alkaloids, with many of which it forms crystalline precipitates. It is also sometimes fraudulently added to beer and to other food articles, to communicate to them either a bitter taste or a yellow color.

**ANALYTICAL CHARACTERS.**—(1.) Its intensely bitter taste. (2.) Its alcoholic solution, when shaken with a potassium salt, gives a yellow, crystalline ppt. (3.) An ammoniacal solution of cupric sulphate gives a green, crystalline ppt. (4.) Glucose, heated with a dilute alkaline solution of picric acid, communicates to it a blood-red color. (5.) Warmed with an alkaline solution of potassium cyanid, an intense red color is produced (the same effect is produced by ammonium sulphhydrate). (6.) Unbleached wool, immersed in boiling solution of picric acid, is dyed yellow.

Nos. 1, 3, 5, and 6 are quite delicate.

When taken internally in overdose, it acts as a poison; it may be separated from animal fluids or from beer by evaporation to a syrup, extracting with 95 per cent. alcohol, acidulated with  $\text{H}_2\text{SO}_4$ ; filtering; evaporating; and applying the tests to a solution of the residue.

**Amido-phenols— $\text{C}_6\text{H}_4, \text{OH}, \text{NH}_2$ .**—Three are known, ortho-, meta- and para-, obtained by the action of reducing agents upon the corresponding nitro-compounds. Their methylic ethers,  $\text{C}_6\text{H}_4, \text{O}(\text{CH}_3)\text{NH}_2$ , are known as anisidins; and their ethylic ethers,  $\text{C}_6\text{H}_4, \text{O}(\text{C}_2\text{H}_5)\text{NH}_2$ , as phenetidins.

By the action of glacial acetic acid upon paraphenetidin, an aceto-derivative, para-acetphenetidin,  $\text{C}_6\text{H}_4, \text{O}(\text{C}_2\text{H}_5)_{(1)}, \text{NH}(\text{C}_2\text{H}_5\text{O})_{(1)}$ , is formed. It has been recommended as an antipyretic, under the name phenacetine, and is a reddish, odorless, tasteless powder, sparingly soluble in  $\text{H}_2\text{O}$ , readily soluble in alcohol. Its hot aqueous solution is colored violet, changing to ruby-red, by chlorin water. The corresponding anisidin, para-acetanisidin;  $\text{C}_6\text{H}_4, \text{O}(\text{CH}_3)_{(1)}, \text{NH}(\text{C}_2\text{H}_5\text{O})_{(1)}$ , has also been suggested as a therapeutic agent. It crystallizes in white, shining, tasteless, odorless scales, fuses at  $127^\circ$  ( $260^\circ, 6 \text{ F.}$ ), sparingly soluble in  $\text{H}_2\text{O}$ , readily soluble in alcohol.

## DIATOMIC PHENOLS.

Diatomic phenols are derived from the benzene series of hydrocarbons by the substitution of two (OH) groups for two atoms of hydrogen. In obedience to the laws of substitution already discussed, three such compounds exist, corresponding to each hydrocarbon. Thus, in the case of benzene:

Ortho.  
1—2  
Pyrocatechin.

Meta.  
1—3  
Resorcin.

Para.  
1—4  
Hydroquinone.

**Pyrocatechin**—*Oxyphenic acid*—*Orthodioxo-benzene*— $\text{C}_6\text{H}_4(\text{OH})_2$ —1—2—is obtained from catechin or from morintannic acid by dry distillation; also by the action of KHO on orthochlor- or orthoiodo-phenol, or by decomposing its methyl ether, guaiacol, by HI at 200° (392° F.). It crystallizes in short, square prisms; fuses at 104° (219°.2 F.), and boils at 245°.5 (473°.9 F.). Readily soluble in water, alcohol, and ether. Its aqueous solution gives a dark green color with  $\text{Fe}_2\text{Cl}_6$  solution, changing to violet on addition of  $\text{NH}_4\text{IPO}$ ,  $\text{NaHCO}_3$ , or tartaric acid.

**Resorcin**—*Metadioxo-benzene*— $\text{C}_6\text{H}_4(\text{OH})_2$ —1—3—is obtained by the action of fused KHO on parachlor- or iodo-phenol. It is usually prepared by dry distillation of extract of Brazil wood.

It forms short, thick, colorless and odorless, rhombic prisms. Fuses at 104° (219°.2 F.), and boils at 271° (519°.8 F.). It is very soluble in water, alcohol, and ether. Its aqueous solution is neutral in reaction, and intensely sweet. With  $\text{Fe}_2\text{Cl}_6$  its solutions assume a dark violet color, which is discharged by  $\text{NH}_4\text{HO}$ . Its ammoniacal solution, by exposure to air, assumes a pink color, changing to brown and, on evaporation, green and dark blue. Heated with phthalic anhydrid at 195° (383° F.) it yields fluorescein (see page 404). It dissolves in fuming  $\text{H}_2\text{SO}_4$ , forming an orange-red solution, which becomes darker, changes to greenish-black, then to pure blue, and finally to purple on being warmed.

Resorcin, heated with sodium nitrite and  $\text{H}_2\text{O}$  to about 150° (302° F.) yields a blue pigment known as lacmoid, which behaves like litmus with acids and alkalies, but is more sensitive.

Resorcin has been recently used in medical practice.

**Hydroquinone**—*Paradioxo-benzene*— $\text{C}_6\text{H}_4(\text{OH})_2$ —1—4—is formed by fusing paraiodo-phenol with KHO at 180° (356° F.), by dry distillation of oxysalicyclic acid or of quinic acid, and by the action of reducing agents on *quinone*. It forms colorless, rhombic prisms, which fuse at 169° (336°.2 F.). Readily soluble in water, alcohol, or ether. Its aqueous solution is turned red-brown by  $\text{NH}_4\text{HO}$ . Oxidizing agents convert it into quinone.

**Quinone**— $\text{C}_6\text{H}_4(\text{OO})_2$ —is the representative of a number of similar compounds, derivable from the aromatic hydrocarbons. It is produced by the oxidizing action of  $\text{MnO}_2 + \text{H}_2\text{SO}_4$ , or of dilute chromic acid, upon quite a number of para-benzene derivatives; but best by the limited oxidation of quinic acid.

It crystallizes in yellow prisms; fuses at  $116^\circ$  ( $240.8^\circ \text{F.}$ ); sublimes at ordinary temperatures; is sparingly soluble in cold, but readily soluble in hot water and in alcohol or ether. It gives off a peculiar, pungent odor, and stimulates the lachrymal secretion. Reducing agents convert it into hydroquinone.

There is no similar substance known corresponding either to pyrocatechin or to resorcin.

**Orsin**—*Dimethoxy-toluene*— $\text{C}_6\text{H}_3(\text{CH}_3)_2(\text{OH})_2$ —exists in nature in those lichens which are used as sources of archil and litmus (*Rocella tinctoria*, etc.). It crystallizes in six-sided prisms; is sweet; readily soluble in water, alcohol, or ether; fuses at  $58^\circ$  ( $136.4^\circ \text{F.}$ ). Its aqueous solution is colored violet-blue by  $\text{Fe}_2\text{Cl}_6$ . It unites with  $\text{NH}_3$  to form a compound which absorbs O from the air, and is converted into orcein,  $\text{C}_6\text{H}_3\text{NO}_3$ ; a dark red or purple body, which is the chief constituent of the dye-stuff known as archil, cudbear, French purple, and litmus.

## TRIATOMIC PHENOLS.

The only compounds of this class at present known with certainty are two isomeric triatomic phenols, which owe the differences in properties existing between them to a different placing of the OH groups. They are *phloroglucin* and *pyrogallol*.

**Phloroglucin**— $\text{C}_6\text{H}_3(\text{OH})_3$ —126—is obtained by the action of potash upon phloretin, quercitrin, maclurin (see Glucosids), catechin, kino, etc. It crystallizes in rhombic prisms, containing 2 Aq; is very sweet; very soluble in water, alcohol, and ether.

**Pyrogallol**—*Pyrogallie acid*— $\text{C}_6\text{H}_3(\text{OH})_3$ —126—is formed when gallic acid (*q.v.*) is heated to  $200^\circ$  ( $392^\circ \text{F.}$ ). It crystallizes in white needles; neutral in reaction; very soluble in water; very bitter; fuses at  $115^\circ$  ( $239^\circ \text{F.}$ ); boils at  $210^\circ$  ( $410^\circ \text{F.}$ ); poisonous. Its most valuable property is that of absorbing oxygen, for which purpose it is used in the laboratory in the form of a solution of potassium pyrogallate.

When pyrogallol is heated with half its weight of phthalic anhydrid for several hours at  $190$ – $200^\circ$  ( $374$ – $392^\circ \text{F.}$ ) it yields **pyrogallol phthalein**, or **gallein**, a brown-red powder (or green crystals) which dissolves with a brown color in neutral solutions, the color changing to red with a faint excess of alkali.

### PHENOL DYES.

**Aurin**— $C_{12}H_{14}O_3$  and **Rosolic acid**— $C_{20}H_{16}O_3$ —are substances existing in the dye obtained by the action of oxalic acid upon phenol in presence of  $H_2SO_4$ , known as corallin or pœonin, which communicates to silk or wool a fine yellow-red color.

Aurin crystallizes in fine, red needles from its solution in HCl. It is insoluble in  $H_2O$ , but soluble in HCl, alcohol, and glacial acetic acid. It forms a colorless compound with potassium bisulphite.

**Phthaleins.**—These substances are produced by heating the phenols with phthalic anhydrid,  $C_6H_4O_3$ , water being at the same time eliminated.

Their constitution is that of a benzene nucleus, two of whose H atoms have been replaced by two acetone groups (CO), whose remaining valences attach them to two phenol groups by exchange with an atom of hydrogen.

Thus phenol-phthalein, the simplest of the group, has the constitution  $C_6H_4 \begin{smallmatrix} \diagup CO-C_6H_4(OH) \\ \diagdown CO-C_6H_4(OH) \end{smallmatrix}$ . Phenol-phthalein is a yellow, crystalline powder, insoluble in water, but soluble in alcohol. Its alcoholic solution, perfectly colorless if neutral, assumes a brilliant magenta-red in the presence of an alkali. This property renders phenol-phthalein very valuable as an *indicator* of reaction.

**Resorcin-phthalein—Fluorescein**— $C_{20}H_{12}O_5$ —bears the same relation to resorcin that phenol-phthalein does to phenol, and is obtained from resorcin by a corresponding method. It is a dark brown crystalline powder, which dissolves in ammonia to form a red solution, exhibiting a most brilliant green fluorescence. A tetrabromo-derivative of fluorescein is used as a dye under the name eosin.

### AROMATIC ALCOHOLS.

The alcohols corresponding to this series of hydrocarbons have the same composition as the corresponding phenols, from which they differ in constitution, and in having the functions of true alcohols. They yield on oxidation, first an aldehyde and then an acid, and they contain the characterizing group of the primary alcohols,  $CH_2OH$ ; once if the alcohol be monoatomic, twice if diatomic, etc. Thus:

As they contain the benzene nucleus, they are capable of yielding isomeric products of further substitution, ortho, para, or meta, according to the position of the substituted atom or radical.

**Benzyl alcohol—Benzoic alcohol—Benzyl hydrate— $C_6H_5(CH_2OH)$ —108**—does not exist in nature, and is of interest chiefly as corresponding to two important compounds, benzoic acid and benzoic aldehyde (oil of bitter almonds). It is obtained by the action of potassium hydrate upon oil of bitter almonds, or by slowly adding sodium amalgam to a boiling solution of benzoic acid.

It is a colorless liquid; boils at  $206.5$  ( $403.7$  F.); has an aromatic odor; is insoluble in water, soluble in all proportions in alcohol, ether, and carbon disulphid. By oxidation it yields, first, benzoic aldehyde,  $C_6H_5(COH)$ ; and afterward, benzoic acid,  $C_6H_5(COOH)$ . By the same means it may be made to yield products similar to those obtained from the alcohols of the saturated hydrocarbons.

### ALPHENOLS.

These substances are intermediate in function between the alcohols and the phenols, and contain both substituted groups (OH) and  $CH_2OH$ .

**Saligenin,  $C_6H_4$   $\begin{smallmatrix} \text{CH}_2\text{OH} \\ \text{OH} \end{smallmatrix}$ —124**—is obtained from salicin (*q. v.*) in large, tabular crystals; quite soluble in alcohol, water, and ether. Oxidizing agents convert it into salicylic aldehyde, which by further oxidation yields salicylic acid. It is also formed by the action of nascent hydrogen on salicylic aldehyde.

### ALDEHYDES.

**Benzoic aldehyde—Benzoyl hydrid— $C_6H_5(COH)$ —106**—is the main constituent of oil of bitter almonds, although it does not exist in the almonds (see p. 436); it is formed, along with hydrocyanic acid and glucose, by the action of water upon amygdalin. It is also formed by a number of general methods of producing aldehydes; by the dehydration of benzylic alcohol; by the dry distillation of a mixture in molecular proportions of calcium benzoate and formate; by the action of nascent hydrogen upon benzoyl cyanid, etc.

It is obtained from bitter almonds. The crude oil contains, besides benzoic aldehyde, hydrocyanic and benzoic acids and cyanobenzoyl. To purify it, it is treated with three to four times its volume of a concentrated solution of sodium bisulphite: the crystalline mass is expressed, dissolved in a small quantity of

water, and decomposed with a concentrated solution of sodium carbonate—the treatment being repeated, if necessary.

It is a colorless oil, having an acrid taste and the odor of bitter almonds; sp. gr. 1.043; boils at 179.4 (354.9 F.); soluble in 30 parts of water, and in all proportions in alcohol and ether. Oxidizing agents convert it into benzoic acid, a change which occurs by mere exposure to air. Nascent hydrogen converts it into benzylic alcohol. With Cl and Br it forms benzoyl chlorid or bromid.  $\text{H}_2\text{SO}_4$  dissolves it when heated, forming a purple-red color, which turns black if more strongly heated.

When perfectly pure, benzoic aldehyde exerts no deleterious action when taken internally; owing, however, to the difficulty of completely removing the hydrocyanic acid, the substances usually sold as *oil of bitter almonds*, *ratafia*, and *almond flavor*, are almost always poisonous, if taken in sufficient quantity. They may contain as much as 10–15 per cent. of hydrocyanic acid, although said to be “purified.” The presence of the poisonous substances may be detected by the tests given on page 292.

**Salicylic aldehyde**—*Salicyl hydrid*—*Salicylal*—*Salicylous acid*— $\text{C}_6\text{H}_4(\text{OH})(\text{COH})$ —122—exists in the flowers of *Spiraea ulmaria*, and is the principal ingredient of the essential oil of that plant. It is best obtained by oxidizing salicin (*q.v.*).

It is a colorless oil; turns red on exposure to air; has an agreeable, aromatic odor, and a sharp, burning taste; sp. gr. 1.173 at 13.5 (56.3 F.); boils at 196.5 (385.7 F.); soluble in water, more so in alcohol and ether.

It is, as we should suspect from its origin, a substance of mixed function, possessing the characteristic properties of aldehyde and phenol. It produces a great number of derivatives, some of which have the characters of salts and ethers.

**Methyl-protocatechuic aldehyde**—**Vanillin**— $\text{C}_6\text{H}_3(\text{OH})(\text{OCH}_3)(\text{COH})$ —is the odoriferous principle of vanilla. It is produced artificially by oxidation of **coniferin**,  $\text{C}_{16}\text{H}_{22}\text{O}_8$ , a glucosid occurring in coniferous plants. It crystallizes in needles, fuses at 80 (176 F.); is sparingly soluble in water, readily soluble in alcohol or ether. It has a pungent taste, and a faint odor of vanilla, the latter more marked, when the substance is heated. On exposure to air it becomes partially oxidized to **vanillic acid**  $\text{C}_8\text{H}_6\text{O}_4$ .

## KETONES.

The ketones of this series are produced by the union of a benzene nucleus with an alcoholic radical through a group  $(\text{CO})$  thus:  $\text{C}_6\text{H}_5, \text{CO}, \text{CH}_3$ . They are also called **phenones**.

**Phenyl methyl ketone**—**Aceto-phenone**—**Hypnone**— $\text{C}_6\text{H}_5, \text{CO}, \text{CH}_3$ —is obtained by distilling a mixture of calcium benzoate and

acetate; or by the action of zinc-methyl upon benzoyl chlorid. It forms large crystalline plates, fusible at 14 (57.2 F.). It has been used as a hypnotic

## ACIDS CORRESPONDING TO THE AROMATIC HYDRATES.

The acids possibly derivable from benzene by the substitution of (COOH), or of (COOH) and (OH), for atoms of hydrogen, would form, were they all known, a great number of series; there are, however, comparatively few of them which have been as yet obtained, although the number of acid series known is greater than that of corresponding alcohols. Each series of mono and diatomic alcohols furnishes a corresponding series of acids, thus:

Benzoic alcohol.

Toluyl glycol.

Saligenin.

Benzoic acid.

Terephthalic acid.

Salicylic acid.

By the progressive substitution of groups (COOH) for atoms of hydrogen in benzene, we may obtain six series of acids, five of which have been isolated:

There may also be three distinct series of bi- tri- and tetra- acids produced by differences in orientation (see p. 391), according as the groups COOH occupy consecutive, symmetrical or unsymmetrical positions.

The alphenols, containing a single group (OH), are at present represented by a single series:

Corresponding to unknown alphenols, containing a greater number of (OH) groups, there are at present two series of acids known:

and

In each of these series the basicity is, as usual, equal to the number of groups ( $\text{COOH}$ ).

**Benzoic acid**—**Acidum benzoicum** (U. S.)— $\text{C}_6\text{H}_5(\text{COOH})$ —122—exists ready formed in benzoin, tolu balsam, castoreum, and several resins. It does not exist in animal nature, so far as is at present known; in those situations in which it has been found, it has resulted from decomposition of hippuric acid (*q. t.*), or has been introduced from without. When taken in moderate doses, it does not pass out in its own form, but is converted into hippuric acid; in excessive doses a portion is eliminated unchanged in the urine. It is obtained from benzoin, or from the urine of herbivorous animals; and is formed in a variety of reactions.

It crystallizes in white, transparent plates; odorless; acid; fuses at 122 ( $251.6^\circ \text{F.}$ ); sublimes at 145 ( $293^\circ \text{F.}$ ); boils at  $240^\circ$  ( $464^\circ \text{F.}$ ); sparingly soluble in cold water; soluble in hot water, alcohol, and ether. Dilute  $\text{HNO}_3$  does not attack it. It dissolves in ordinary  $\text{H}_2\text{SO}_4$ , and is precipitated unchanged by  $\text{H}_2\text{O}$ . Its salts are all soluble.

From it are produced many derivatives by the further substitution of atoms or radicals for one or more of the atoms of H remaining in the  $\text{C}_6\text{H}_5$  group.

**Hippuric acid**—**Benzyl-glycocol**—**Benzyl-amido-acetic acid**— $\text{CH}_2[\text{NO}(\text{C}_6\text{H}_5\text{CO})]\text{COOH}$ —179—is a constant constituent of the urine of the herbivora, and of human urine to the extent of 0.29–2.84 grams (4.5–43.8 grains) in 24 hours. It is more abundant with a purely vegetable diet, after the administration of benzoic acid, and in diabetes mellitus and chorea.

It crystallizes in transparent, colorless, odorless, bitter prisms; sparingly soluble in water; fuses at  $130^\circ$  ( $266^\circ \text{F.}$ ). It dissolves unchanged in  $\text{HCl}$ ; but on boiling the solution it is decomposed into benzoic acid and glycocol. The same decomposition is effected by dilute  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , and oxalic acid, and by a ferment developed in putrefying urine. Oxidizing agents convert it into benzoic acid, benzamid, and  $\text{CO}_2$ .

The characters of hippuric acid are: (1) when heated in a dry tube it fuses and gives off a sublimate of benzoic acid and an odor of hydrocyanic acid; (2) it gives a brown ppt. with ferric chlorid; (3) when heated with lime it gives off benzene and ammonia.

**Salicylic acids**—**Oxybenzoic acids**.—Three are known, ortho, meta and para. The **Acidum salicylicum** (U. S.),  $\text{C}_6\text{H}_4(\text{OH})(\text{COOH})$ , is the ortho acid (1, 2)—138. It was first obtained from essence of *spiraea*, which consists largely of salicylic aldehyde, and subsequently from oil of wintergreen (*gaultheria*), which contains methyl salicylate, and also from *salicin*, a glucosid; yielding salicylic aldehyde. It is now obtained from phenol. This is fused, and, while a current of dry  $\text{CO}_2$  is passed through it, small por-

tions of Na are added ; the sodium salicylate thus formed is dissolved in  $H_2O$  and decomposed with  $HCl$ , when the liberated salicylic acid is precipitated.

It crystallizes in fine white needles ; very sparingly soluble in cold water, quite soluble in hot water, alcohol, and ether ; it fuses at  $158^\circ$  ( $316.4^\circ F.$ ), and may be distilled with but slight decomposition, if it be pure.  $Cl$  and  $Br$  form with it products of substitution. Fuming  $HNO_3$  forms with it a nitro-derivative and, if the action be prolonged, converts it into pieric acid. With ferric chlorid, its aqueous solution assumes a fine violet color.

The meta- and para- acids are obtained by fusing meta- or para-chloro- bromo- or iodo-benzoic acid with  $KHO$ .

Salicylic acid and its salts (it is monobasic, although diatomic) are extensively used in medicine, both externally as antiseptics and internally in the treatment of rheumatism, etc. It is not without caustic properties, and hence, when taken internally, it should be largely diluted.

Phenyl salicylate— $C_6H_4.OH.COO.C_6H_5$ —has been used as an antiseptic and antipyretic under the name **salol**. It is a white crystalline powder, tasteless ; fusible at  $42^\circ$  ( $107.4^\circ F.$ ) ; soluble in  $H_2O$  and in alcohol, ether and benzol. The corresponding  $\beta$  naphthol (*q. v.*) compound,  $C_{10}H_7.OH.COO.C_6H_5$ , is a colorless, odorless, and tasteless substance, insoluble in  $H_2O$ . It has been used for the same purposes as salol under the names **naphthalol** and **naphthol-salol**.

Gallic acid—*Acidum gallicum* (*U. S.*)— $C_6H_2(OH)_3COOH$ —170—exists in nature in certain leaves, seeds, and fruits. It is best obtained from gall-nuts, which contain its glucosid, gallotannic acid (*q. v.*). It can be obtained from salicylic acid.

It crystallizes in long silky needles with 1  $Aq$  ; odorless ; acidulous in taste ; sparingly soluble in cold water, very soluble in hot water and in alcohol ; its solutions are acid. When heated to  $210-215^\circ$  ( $410-419^\circ F.$ ) it yields  $CO_2$  and pyrogallol (*q. v.*). Its solution does not precipitate gelatin, nor the salts of the alkaloids, as does tannin. It forms four series of salts.

## SULPHONIC ACIDS.

The sulphonic acids corresponding to the series  $C_nH_{2n-6}$  are derived from the hydrocarbons by the substitution of one or more groups ( $SO_3H$ ) for one or more  $H$  atoms of the hydrocarbons. They are produced by the action of fuming sulphuric acid upon the hydrocarbons, and are mono-, bi- or polysubstituted, according to the degree of concentration of the acid used, and the temperature at which the action takes place. They are strong

acids, forming soluble and crystalline salts. Their basicity varies with the number of  $(\text{SO}_3\text{H})$  groups which they contain.

**Benzo-monosulphonic acid**— $\text{C}_6\text{H}_5.\text{SO}_3\text{H}$ —is formed by dissolving benzene in weak fuming sulphuric acid at a slightly elevated temperature, and diluting with  $\text{H}_2\text{O}$ . It crystallizes in extremely soluble, deliquescent plates with  $1\frac{1}{2}$  Aq.

Three benzo-disulphonic acids— $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$ —ortho-, meta- and para-, are known, also one benzo-trisulphonic acid— $\text{C}_6\text{H}_3(\text{SO}_3\text{H})_3$ .

Three toluo-sulphonic acids— $\text{C}_6\text{H}_4\text{CH}_3.\text{SO}_3\text{H}$ —ortho-, meta- and para-, have been obtained. By the action of a mixture of ordinary and fuming sulphuric acids upon toluene at a temperature not exceeding  $100^\circ$  ( $212^\circ\text{F.}$ ), a mixture of the ortho- and para-acids is produced. When this is treated with  $\text{PCl}_5$ , it is converted into a mixture of para- and ortho-toluene sulphonic chlorids— $\text{C}_6\text{H}_4\text{CH}_3.\text{SO}_2\text{Cl}$ . The ortho-chlorid, when acted on by dry ammonia and ammonium carbonate, is converted into ortho-toluene sulphimid— $\text{C}_6\text{H}_4\text{CH}_3.\text{SO}_2\text{NH}_2$ . This product, when oxidized by potassium permanganate, is converted into benzyl-sulphonic imid— $\text{C}_6\text{H}_5.\text{CO}.\text{SO}_2\text{NH}_2$ —or saccharin—an odorless, crystalline powder, having great sweetening power, its sweet taste being still detectable in a dilution of 1-50,000. Sparingly soluble in water and in ether, readily in alcohol. Its solutions are acid in reaction. When heated with  $\text{Na}_2\text{CO}_3$  it is carbonized and gives off an odor of benzene. It is not attacked by  $\text{H}_2\text{SO}_4$ .

Another series of sulphonic derivatives is obtained from the phenols. Among them is:

**Ortho-phenol sulphonic acid**—Sozolic acid—Aseptol— $\text{C}_6\text{H}_4.\text{OH}.\text{SO}_3\text{H}$ —which is prepared by the action of cold concentrated  $\text{H}_2\text{SO}_4$  upon phenol. It is a reddish, syrupy liquid, soluble in  $\text{H}_2\text{O}$  in all proportions, has a faint and not disagreeable odor. It prevents fermentation and putrefaction, and is a non-poisonous, non-irritant antiseptic. The salts of this and the corresponding para- and meta-acids have been used as antiseptics and insecticides, under the name of sulpho-carbolates, *e.g.*, Sodii sulpho-carbolas (**U. S.**).

**Salicyl sulphonic acid**— $\text{C}_6\text{H}_4.\text{OH}.\text{COOH}.\text{SO}_3\text{H}$ —is a crystalline solid formed by the action of strong  $\text{H}_2\text{SO}_4$  on salicylic acid. It is easily soluble in  $\text{H}_2\text{O}$ . It has been recommended as a test for albumin.

### NITRO-DERIVATIVES OF BENZENE.

By substitution of the univalent radical  $(\text{NO}_2)$  for the hydrogen of benzene a series of substitution products are obtainable, corresponding to the series of haloid derivatives, phenols, etc. (see pp. 391-394).

**Mono-nitro-benzene—Nitro-benzol—Nitro-benzene—Essence of Mirbane— $C_6H_5NO_2$ —123**—is obtained by the moderated action of fuming  $HNO_3$  or of a mixture of  $HNO_3$  and  $H_2SO_4$  on benzene.

It is a yellow, sweet liquid, with an odor of bitter almonds; sp. gr. 1.209 at 15° (59° F.); boils at 213° (415.4° F.); almost insoluble in water; very soluble in alcohol and ether. Concentrated  $H_2SO_4$  dissolves, and, when boiling, decomposes it. Boiled with fuming  $HNO_3$ , it is converted into binitro-benzene. It is converted into *anilin* by reducing agents.

It has been used in perfumery as *artificial essence of bitter almonds*; but as inhalation of its vapor, even largely diluted with air, causes headache, drowsiness, difficulty of respiration, cardiac irregularity, loss of muscular power, convulsions, and coma, its use for that purpose is to be condemned. Taken internally it is an active poison.

Nitro-benzol may be distinguished from oil of bitter almonds (benzoic aldehyde) by  $H_2SO_4$ , which does not color the former; and by the action of acetic acid and iron filings, which convert nitro-benzene into anilin, whose presence is detected by the reactions for that substance (*q.v.*).

## AMIDO-DERIVATIVES OF BENZENE.

These substances are derivable from benzene and its homologues by the substitution of one or more univalent groups ( $NH_2$ ) (amidogen) for atoms of hydrogen. They may also be considered as phenylamins, produced by the substitution of the univalent radical phenyl ( $C_6H_5$ ), or its homologues, derivable from the benzene nucleus, for the hydrogen of ammonia. They all are strongly basic in character.

**Anilin—Amido-benzene—Amido-benzol—Phenylamin—Kyanol—Cristallin— $C_6H_5NH_2$ —N—93**—exists in small quantity in coal-tar and is one of the products of the destructive distillation of indigo. It is prepared by the reduction of nitro-benzene by hydrogen:  $C_6H_5NO_2 + 3H_2 = C_6H_5(NH_2) + 2H_2O$ ; the hydrogen being liberated in the nascent state in contact with nitro-benzene by the action of iron filings on acetic acid.

Pure anilin is a colorless liquid; has a peculiar, aromatic odor, and an acrid, burning taste; sp. gr. 1.02 at 16° (60.8° F.); boils at 184.8° (364.6° F.); crystallizes at -8° (17.6° F.); soluble in 31 pts. of cold water, soluble in all proportions in alcohol, ether, carbon disulphid, etc. When exposed to air, it turns brown, the color of the commercial "oil," and, finally, resinifies. It is neutral in reaction. Oxidizing agents convert it into blue, violet, red, green,

or black derivatives. Cl, Br, and I act upon it violently to produce products of substitution. Concentrated  $\text{H}_2\text{SO}_4$  converts it, according to the conditions, into **sulphanilic** or **disulphanilic acid**. With acids it unites, after the manner of the ammonia, without liberation of  $\text{H}_2\text{O}$  or  $\text{H}$ , to form salts, most of which are crystallizable, soluble in water, and colorless, although by exposure to air, especially if moist, they turn red. The sulphate has been used medicinally.

Anilin itself, when taken in the liquid form or by inhalation, is an active poison, producing symptoms similar to those caused by nitro-benzene (*q.v.*). Its salts, if pure, seem to have but slight deleterious action.

Anilin may be recognized by the following reactions: (1.) With a nitrate and  $\text{H}_2\text{SO}_4$ , a red color. (2.) Cold  $\text{H}_2\text{SO}_4$  does not color it alone; on addition of potassium dichromate, a fine blue color is produced, which, on dilution with water, passes to violet, and, if not diluted, to black. (3.) With calcium hypochlorite, a violet color. (4.) Heated with cupric chlorate, a black color. (5.) Heated with mercuric chlorid, a deep crimson color.

### DERIVATIVES OF ANILIN.

By the substitution of other radicals or elements for the remaining hydrogen atoms of the benzene nucleus, or for the hydrogen atoms of the amidogen group,  $\text{NH}_2$ , a great number of derivatives, including many isomeres, are produced.

In all of these derivatives the group ( $\text{NH}_2$ ) is considered as occupying the position 1.

**Chloranilins.**—Three monochloranilins are known, of which two, ortho- (1—2) and meta- (1—3), are liquid. The other, para- (1—4), is solid and crystalline.

Four dichloranilins, 1—2—4, 1—2—5, 1—3—5, and 1—3—4, are known, all solid and crystalline.

Two trichloranilins, 1—2—4—6 and 1—2—4—5, are known, both solid and crystalline.

The corresponding bromanilins are also known: also a tetrabromanilin, 1—2—3—4—6, and a pentabromanilin,  $\text{C}_6(\text{NH}_2)\text{Br}_5$ .

Of the possible iodanilins, but four have been described: **Meta-moniodanilin** (1—3); **paramoniodanilin** (1—4); the **diiodanilin** (1—2—4); and the **triiodanilin** (1—2—4—6).

**Nitranilins.**—The three isomeres, ortho-, meta-, and paramonitranilins,  $\text{C}_6\text{H}_3(\text{NH}_2)(\text{NO}_2)_2$ , are formed by imperfect reduction of the dinitro-benzenes.

Two dinitranilins,  $\text{C}_6\text{H}_3(\text{NH}_2)(\text{NO}_2)_2$  (1—2—4) and (1—2—6), are known.

A single trinitranilin,  $C_6H_2(NH_2)(NO_2)_3$  (1—2—4—6), has been obtained by the action of alcoholic ammonia upon the ethylic or methylic ether of picric acid. It is also called picramid.

**Anilids.**—These are compounds in which one of the H atoms of the amidogen group has been replaced by an acid radical. Or they may also be considered as amids, whose remaining hydrogen has been more or less replaced by phenyl,  $C_6H_5$ .

**Acetanilid—Antifebrin—Phenyl-acetamid— $C_6H_5(NH.C_2H_3O)$** —is obtained either by heating together anilin and glacial acetic acid for several hours, or, better, by the action of acetyl chlorid on anilin. It forms colorless, shining, crystalline scales; fuses at  $112.5$  ( $234.5$  F.), and volatilizes unchanged at  $295$  ( $563$  F.). It is sparingly soluble in cold water, soluble in hot water and in alcohol.

When acetanilid is heated with an equal weight of  $ZnCl_2$ , flavanilin, a colored substance having a fine green fluorescence, and soluble in warm dilute HCl, is produced.

By herbivorous animals acetanilid is eliminated as para-amido phenol,  $C_6H_4.OH_1.NH_2_4$ ; by carnivorous animals partly in that form, but mostly as orthoxy-carbanil,  $C_6H_4.NO.CO.H$ .

By the further substitution of a group ( $CH_3$ ) in acetanilid, methyl-acetanilid, or exalgin,  $C_6H_5.N.(CH_3).C_2H_3O$  is produced. It is formed by the action of methyl iodid upon sodium acetanilid,  $C_6H_5.NNa.C_2H_3O$ . It is a crystalline solid, sparingly soluble in  $H_2O$ , readily in dilute alcohol. Its odor is faintly aromatic.

Three acetoluids,  $C_6H_4.CH_3.NH.C_2H_3O$ , ortho, meta, and para, are also known. The para- and meta- compounds seem to be almost inert, while the ortho- compound is highly poisonous.

The "anilin dyes" now so extensively used, even those made from anilin, are not compounds of anilin, but are salts of bases formed from it, themselves colorless, called rosanilins (see p. 422).

**Phenylamins—Phenylendiamins, etc.**—Anilin is the simplest representative of a large class of substances. It may be considered as benzene in which H has been replaced by  $NH_2$ , thus:  $C_6H_5.NH_2$ . Its superior homologues, derivable from the superior homologues of benzene, each have at least three isomeres, ortho-, meta- and para-, according to the orientation of the groups  $NH_2$  and  $C_nH_{2n+1}$ . Anilin may also be considered as ammonia in which H has been replaced by phenyl,  $C_6H_5$ , thus being a primary monamin (see p. 274),  $\left( \begin{smallmatrix} C_6H_5 \\ H_2 \end{smallmatrix} \right) N$ . The remaining two H atoms may be replaced by other radicals to form an almost infinite variety of secondary and tertiary phenylamins, precisely as in the case of the alcoholic monamins.

Again, it is clear that, considering anilin as amido-benzene, the

substitution of  $\text{NH}_2$  is not necessarily limited to the introduction of one such group. There may be three phenylendiamins,  $\text{C}_6\text{H}_4(\text{NH}_2)_2$ , ortho-, meta- and para-, three triamido benzenes,  $\text{C}_6\text{H}_3(\text{NH}_2)_3$ , etc.

When it is remembered that each one of these compounds is capable of forming a large number of derivatives by further substitution, and a series of salts, it is plain that the chemistry of these compounds would easily fill a volume.

### HYDRAZINS.

The hydrazins are theoretically derivable from the group  $\text{H}_2\text{N}-\text{NH}_2$ , diamidogen, by the substitution of acid, alcoholic, or phenylic radicals for one or more of the hydrogen atoms.

Phenyl hydrazin— $\text{C}_6\text{H}_5-\text{HN}-\text{NH}_2$ —is obtained by the action of zinc-dust and acetic acid on diazo-amidobenzene. It is a yellow oil, sparingly soluble in water, soluble in alcohol and in ether, possessed of strong reducing power, and acting as a monacid base to form crystallized salts.

Phenyl-acetyl-hydrazin — Hydracetin— $\text{C}_6\text{H}_5-\text{HN}-\text{NH}-\text{C}_2\text{H}_5\text{O}$ —is produced by the action of acetyl chlorid, or of acetic anhydrid, upon phenyl hydrazin. It is a white, tasteless, odorless, crystalline powder, sparingly soluble in  $\text{H}_2\text{O}$ , readily soluble in alcohol. It acts as a reducing agent. It is the active ingredient in the antipyretic known as **pyrodin**.

### AZO AND DIAZO DERIVATIVES.

The azo compounds are derivable from the aromatic hydrocarbons by loss of two H atoms from two molecules of the hydrocarbon, and union of the remainders through the intermediary of a group  $(-\text{N}=\text{N}-)$ . They are formed by the action of certain reducing agents upon the nitro-derivatives, and may be considered as intermediary products in the reduction of the nitro-derivatives to amines. Thus in the case of benzene :

The diazo compounds consist of an univalent remainder of an aromatic hydrocarbon, united by the group ( $-N=N-$ ) with a haloid atom, or an acid residue:  $C_6H_5-N=N-Br$  = Diazobenzene bromid.

## PYRIDIN BASES.

These interesting substances, closely related to the vegetable alkaloids, as well as to some of the alkaloids produced during putrefactive decomposition of animal matters, were first discovered in 1851, as constituents of oil of Dippel = oleum animale = oleum cornu cervi = bone-oil, an oil produced during the dry distillation of bones, horns, etc., and as a by-product in the manufacture of ammoniacal compounds from those sources. They also occur in coal-tar, naphtha, and in commercial ammonia, methylic spirit, and fusel oil.

The pyridin bases at present known are:

	Formula.	Boiling-point.	Sp. gr. at 22°.
Pyridin.....	$C_5H_5N$	115°	0.924
Picolin.....	$C_6H_7N$	134°	0.933
Lutidin.....	$C_7H_9N$	154°	0.945
Collidin.....	$C_8H_{11}N$	170°	0.953
Parvolin.....	$C_9H_{13}N$	188°	0.966
Coridin.....	$C_{10}H_{15}N$	211°	0.974
Rubidin.....	$C_{11}H_{17}N$	230°	1.017
Viridin.....	$C_{12}H_{19}N$	251°	1.024

It will be observed that these compounds are metameric with the anilins, from which they differ in constitution, as shown by the structural formulæ of picolin and anilin:

They are all liquid at the ordinary temperature, behave as tertiary monamins, react with several of the general reagents of the alkaloids, and form chloroplatinates which are decomposed by boiling water.

**Pyridin**— $\text{HC} \begin{smallmatrix} \text{CH}=\text{CH} \\ \text{CH}=\text{CH} \end{smallmatrix} \text{N}$ —is obtained from oil of Dippel, and is also obtainable synthetically from piperidin,  $\text{CH}_2 \begin{smallmatrix} \text{CH}_2-\text{CH}_2 \\ \text{CH}_2-\text{CH}_2 \end{smallmatrix} \text{N}-\text{H}$ , which is itself a derivative of piperin,  $\text{C}_{12}\text{H}_{19}\text{O}_6\text{N}$ , a constituent of black and white pepper.

It is a colorless, mobile liquid, having a peculiar, very penetrating odor. It boils at 115° (239° F.). It mixes with water in all proportions. It is strongly alkaline, and combines with acids as does  $\text{NH}_3$ . Like all the bases of this series, it is very stable, and withstands the action of such oxidizing agents as fuming  $\text{HNO}_3$  and chromic acid. It forms crystalline salts.

**Parvolin**,  $\text{C}_8\text{H}_{13}\text{N}$ ; **Collidin**,  $\text{C}_8\text{H}_{11}\text{N}$ ; and **Hydrocollidin**,  $\text{C}_8\text{H}_{13}\text{N}$ —have been noted as products of putrefactive decomposition of albuminoids.

**Pyrrol**— $\text{HN} \begin{smallmatrix} \text{CH}=\text{CH} \\ \text{CH}=\text{CH} \end{smallmatrix}$ —is a weak base accompanying the pyridin bases in oil of Dippel, and also obtainable from other sources. It is a colorless, oily liquid, whose odor resembles that of chloroform.

By acting upon pyrrol with an ethereal solution of iodine, a quadrisubstituted derivative, tetriodopyrrol,  $\text{C}_4\text{HI}_4\text{N}$ , is obtained as a brown powder, which has been used under the name iodol as a substitute for iodoform in surgical practice.

**Furfural**— $\text{C}_5\text{H}_4\text{O}_2$ —is also a condensation derivative of benzene, formed by the dry distillation of sugar, or by the action of  $\text{ZnCl}_2$  or dilute  $\text{H}_2\text{SO}_4$  on bran. It is a colorless liquid, has an agreeable odor, boils at 162° (323.6° F.), soluble in water and in alcohol. It is an aldehyde and undergoes the reactions common to those substances.

## INCOMPLETE BENZENIC HYDROCARBONS.

SERIES  $C_nH_{2n-8}$  AND  $C_nH_{2n-10}$ .

These may be considered as benzenic compounds which have been rendered incomplete by loss of  $H_2$ , either in the benzene nucleus or in a lateral chain. Thus while ethylbenzene is produced by the addition of a molecule of ethylene to a molecule of benzene:  $C_6H_5.H + CH_2.CH_2 = C_6H_5.CH_2.CH_3$ ; if acetylene be substituted for ethylene, ethylenbenzene is formed:  $C_6H_5.H + CH.CH = C_6H_5.CH.CH_2$ .

**Styrolene—Cinnamene—Ethylenbenzene—Phenylethene—** $C_6H_5$   
 $—CH=CH_2$ —104—exists ready formed in essential oil of styrax. It is also formed by decomposition of cinnamic acid (*q. c.*), or, synthetically, by the action of a red heat upon pure acetylene, a mixture of acetylene and benzene, or a mixture of benzene and ethylene. It is a colorless liquid, has a penetrating odor, recalling those of benzene and naphthalene, and a peppery taste; boils at  $143^\circ$  ( $289.4^\circ F.$ ); soluble in all proportions in alcohol and water; neutral in reaction.

**Phenyl-acetylene—Acetenyl-benzene—** $C_6H_5.C\equiv CH$ —is formed by heating acetophenone chlorid with  $KHO$  in alcoholic solution. It is a colorless liquid, of an aromatic odor, boils at  $140^\circ$  ( $284^\circ F.$ ).

## ALCOHOLS.

SERIES  $C_nH_{2n-6}O$ .

**Cholesteric alcohol—Cholesterin—** $C_{26}H_{44}OH$ —372—is an alcohol, although usually classed by physiologists among the fats, because it is greasy to the touch and soluble in ether.

It occurs in the animal economy, normally in the bile, blood (especially that coming from the brain), nerve-tissue, brain, spleen, sebum, contents of the intestines, meconium, and fæces; pathologically in biliary calculi, in the urine in diabetes and icterus, in the fluids of ascites, hydrocele, etc., in tubercular and cancerous deposits, in cataracts, in atheromatous degenerations, and sometimes in masses of considerable size, in cerebral tumors. It also exists in the vegetable world in peas, beans, olive-oil, wheat, etc. It is best obtained from biliary calculi, the lighter-colored varieties of which consist almost entirely of this substance.

Cholesterin crystallizes with or without  $Aq$ ; from benzene, petroleum, chloroform or anhydrous ether, it separates in delicate, colorless, silky needles, having the composition  $C_{26}H_{44}O$ ; from hot alcohol, or a mixture of alcohol and ether, it crystallizes in

rhombic plates, usually with one obtuse angle wanting, having the composition  $C_{26}H_{44}O + 1 \text{ Aq}$ ; these crystals, transparent at first, become opaque on exposure to air, from loss of Aq. It is insoluble in water, in alkalis and dilute acids, difficultly soluble in cold alcohol, readily soluble in hot alcohol, ether, benzene, acetic acid, glycerin, and solutions of the biliary acids. It is odorless and tasteless. When anhydrous it fuses at  $145$  ( $293^\circ \text{ F.}$ ) and solidifies at  $137$  ( $278.6^\circ \text{ F.}$ ); sp. gr. 1.046. It is lævogyrous,  $[\alpha]_D = 31.6$  in any solvent.

It combines readily with the volatile fatty acids. From its solution in glacial acetic acid a compound having the composition  $C_{26}H_{44}O.C_2H_4O_2$  separates in fine curved crystals, which are decomposed on contact with water or alcohol; when heated with acids under pressure, it forms true ethers. Hot  $HNO_3$  oxidizes it to cholesteric acid,  $C.H_{10}O_5$ , which is also produced by the oxidation of biliary acids: a fact which indicates the probable existence of some relation between the methods of formation of cholesterol and of the biliary acids in the economy.

Cholesterin may be recognized by the following reactions: (1.) Moistened with  $HNO_3$ , and evaporated to dryness, a yellow residue remains, which turns brick-red on addition of  $NH_4HO$ . (2.) It is colored violet when a mixture of 2 vols.  $H_2SO_4$  (or  $HCl$ ) and 1 vol. ferric chlorid solution is evaporated upon it. (3.) When  $H_2SO_4$  is added to a  $CHCl_3$  solution of cholesterin the liquid is colored purple-red, changing during evaporation to blue, green and yellow.

Cholesterin is accompanied in wool fat by an isomere, **ischolesterin**.

Cholesterin combines with the fatty acids to form ethers, corresponding to the fats, and it probably exists in nature largely in such combination. **Lanolin** is a neutral, fatty body consisting of such **cholesterids**, or cholesterin ethers, obtained from suint, or wool fat. It is used as a vehicle in pharmacy, possessing two advantages over the fats and over vaseline: it is rapidly absorbed by the skin, and is miscible with water in all proportions.

### INDIGO GROUP.

In this group are included a number of substances, derivable from indigo-blue, which are evidently closely related to the benzene group, as is shown by the number of benzene derivatives which are obtained by their decomposition, but whose constitution is not yet definitely established.

**Indigotin** — *Indigo-blue* —  $C_{16}H_{10}N_2O_2$  — constitutes the greater part of the commercial *indigo*. It does not exist preformed in the plants from which it is obtained, whose juice is naturally

colorless, but is produced by decomposition of a glucosid contained in them (see Indican, p. 420).

Indigotin may be obtained by the action of phosphorus trichlorid on isatin; or, in a nearly pure form, by cautiously subliming commercial indigo. It forms purple-red, somewhat metallic, orthorhombic prisms or plates, odorless, tasteless, neutral, insoluble in water, ether, or dilute acids or alkalies. By dry distillation it yields anilin and other products. By moderate heating with dilute  $\text{HNO}_3$  it gives off gas and is converted into isatin.

**Indigo Sulphonic Acids.**—When indigo is heated for some time with fuming  $\text{H}_2\text{SO}_4$  it dissolves. If the solution be diluted with  $\text{H}_2\text{O}$ , a blue powder, soluble in  $\text{H}_2\text{O}$ , but insoluble in dilute acids, is precipitated. This is indigo-monosulphonic or phenicin-sulphonic acid— $\text{C}_{16}\text{H}_9\text{N}_2\text{O}_2\text{SO}_3\text{H}$ .

The filtrate from the last-mentioned precipitate contains indigo-disulphonic, sulphindyllic, or sulphindigotic acid— $\text{C}_{16}\text{H}_8\text{N}_2\text{O}_2(\text{SO}_3\text{H})_2$ —whose K and Na salts constitute soluble pastes known in the arts as soluble indigo, or indigocarmine.

**Isatin**— $\text{C}_8\text{H}_5\text{NO}_2$ —obtained by oxidation of indigo-blue, forms shining, transparent, red-brown prisms. It is odorless, sparingly soluble in water, readily soluble in alcohol.

**Dioxindol—Hydrindic acid**— $\text{C}_8\text{H}_7\text{NO}_2$ —is formed by the action of Na on isatin suspended in  $\text{H}_2\text{O}$ . It forms yellow prisms, soluble in  $\text{H}_2\text{O}$ , and combines with both bases and acids.

**Oxindol**— $\text{C}_8\text{H}_7\text{NO}$ —is obtained from dioxindol by reduction with Na amalgam in acid solution. It crystallizes in easily soluble, colorless needles, and combines with acids and bases.

**Indol**— $\text{C}_8\text{H}_7\text{N}$ —is produced by distilling oxindol over zinc-dust, or by heating orthonitrocinnamic acid with KHO and Fe filings.

It crystallizes in large, shining, colorless plates, having the odor of naphthylamin. It is a weak base, forming salts with acids, which are, however, decomposed by boiling water. Its aqueous solution, acidulated with HCl, is colored rose-red by  $\text{KNO}_2$ . It is converted into anilin by fused KHO.

It is one of the products of putrefaction of albuminoid substances, and is formed during the action of the pancreatic secretion upon albuminoids. It is partly eliminated with the fæces and partly reabsorbed.

In the intestine and fæces indol is invariably accompanied by **Skatol**,  $\text{C}_9\text{H}_9\text{N}$ , its superior homologue, which may also be obtained by the action of Sn and HCl on indigo. It crystallizes in brilliant plates, and is less soluble than indigo. The product obtained from indigo has a penetrating but not disagreeable odor, while that obtained from putrid albumin and from faecal or intestinal matter has a disgusting odor, probably due to the presence of foreign substances.

**Indican**— $\text{C}_{26}\text{H}_{31}\text{N}_{17}$ —is a glucosid existing in the different varieties of indigo-producing plants, and also in the urine and blood of man and the herbivora.

It is a yellow or light brown syrup, which cannot be dried without decomposition, bitter and disagreeable to the taste, acid in reaction, and soluble in water, alcohol, and ether.

It is very prone to decomposition. Even slight heating decomposes it into leucin, indicanin,  $\text{C}_{20}\text{H}_{23}\text{NO}_{12}$ , and indiglucin,  $\text{C}_6\text{H}_{10}\text{O}_6$ . A characteristic decomposition is that when heated in acid solution, or under the influence of certain ferments (?), it is decomposed into indigo-blue and indiglucin, the latter a glucose :

## BI- AND POLYBENZOIC HYDROCARBONS.

Among the compounds already considered are several containing more than one benzene nucleus, but in them the union of the two nuclei, as in the azo compounds, is through an element other than carbon. In the compounds now to be considered two or more benzene nuclei are united with each other, either directly, or through the carbon of a linking lateral chain.

## HYDROCARBONS WITH INDIRECTLY UNITED BENZENE NUCLEI.

The simplest of the bi- and polybenzoic hydrocarbons are those in which two or more benzene nuclei are combined with a linking lateral chain. By the substitution of phenyl for the H of methane four compounds can be produced :

Of these the first has been already considered, and the fourth has not been isolated, although the corresponding ethane is known.

**Diphenylmethane—Benzyl-benzene**—is produced by the action of aluminium chlorid upon a mixture of benzyl chlorid and benzene. It is a crystalline solid, fuses at 27° (80.6 F.) and boils at 262° (503.6 F.); soluble in alcohol, ether and chloroform; has an odor resembling that of the orange.

**Triphenylmethane**—is produced by the action of aluminium chlorid upon a mixture of benzene and chloroform. It is a crystalline solid, fuses at 92° (197.6 F.); boils at 360° (680 F.); soluble in ether, and in chloroform. It is converted into a trinitro derivative by fuming  $\text{HNO}_3$ , and this, in turn, is converted by nascent H into leuco-pararosanilin,  $\text{CH}(\text{C}_6\text{H}_4.\text{NH}_2)_3$  (see below).

## DERIVATIVES OF THE PHENYLMETHANES.

**Ketones**— $\text{CO} = (\text{C}_6\text{H}_{2n-1})_2$ .—These substances are similar to the phenones already described, but contain two benzene nuclei in place of one. They are produced by the oxidation of the hydro-

carbons  $C_nH_{2n-14}$ ; by the action of  $P_2O_5$  on a mixture of a hydrocarbon  $C_nH_{2n-6}$  with an acid  $C_nH_{2n-7}CO.OH$ ; and by the action of carbon oxychlorid upon a hydrocarbon  $C_nH_{2n-6}$  in the presence of  $Al_2Cl_6$ .

**Benzophenone — Diphenyl-ketone** —  $CO = (C_6H_5)_2$  — forms large rhombic prisms; fuses at  $48^\circ$  ( $118.4^\circ F.$ ); boils at  $305^\circ$  ( $581^\circ F.$ ); insoluble in  $H_2O$ , soluble in alcohol and ether. It is decomposed by soda-lime into benzene and benzoic acid. Sodium amalgam converts it into benzhydrol, or diphenylcarbinol,  $CH(OH) = (C_6H_5)_2$ , a secondary alcohol.

**Amido-derivatives.**—Among these substances are included some of great industrial interest. Many of the bases, whose salts are the brilliant pigments obtained from anilin and its homologues, are amido-derivatives of triphenylmethane.

**Amido-triphenylmethane** —  $CH.(C_6H_5)_2(C_6H_4.NH_2)$  — is formed by the action of benzhydrol upon anilin chlorid in the presence of  $ZnCl_2$ .

**Diamido-triphenylmethane** —  $CH.(C_6H_5)(C_6H_4.NH_2)_2$  — is produced by the action of anilin chlorid and benzoic aldehyde upon each other in the presence of  $ZnCl_2$ . The salts of this base are blue, and are decomposed by alkalis with liberation of the base, which is a yellow, imperfectly crystalline solid, insoluble in water, soluble in benzene and in alcohol.

The base is converted by  $HgCl_2$  into the corresponding tertiary alcohol, diamido-triphenyl carbinol,  $C(OH).(C_6H_5).(C_6H_4.NH_2)_2$ , whose oxalate or chloro-zincate is malachite green.

**Triamido-triphenylmethane** —  $CH(C_6H_4.NH_2)_3$  — may be obtained by the reduction of para-nitrobenzoic aldehyde by nascent hydrogen, and is also known as *paraleucanilin*. By the action of oxidizing agents it is converted into a tertiary alcohol, *pararosanilin*, or triamido-triphenyl carbinol, which is the type of quite a number of important bodies, among which is *rosanilin*, or diphenyltoluyl carbinol, whose chlorid or acetate is the brilliant red dye known as *anilin red*, *magenta*, *fuchsine*. The relation of these bodies to each other is shown by the following formulæ:

The **rosanilins** are powerful triacid bases, are colorless, but combine with acids to form brilliantly colored salts. Fuchsine is industrially obtained from "anilin oil," which contains both anilin and toluidin, neither of which in the pure state will produce a red color. The process consists essentially in heating the oil with a mixture of nitro-benzene, hydrochloric acid and iron filings. The product is a mixture of the chlorids of rosanilin and pararosanilin, is in hard, green crystals, soluble in water and alcohol, to which it communicates a brilliant red color.

The rosanilins are capable of further modification by the substitution of various radicals for the hydrogen atoms in the benzene nuclei, or in the groups  $\text{NH}_2$ , and by variations in the positions in which such substitution occurs.

**Hoffman's violet**, obtained by heating rosanilin chlorid with methyl iodid, is trimethylrosanilin chlorid. By a further action of methyl iodid, a brilliant green, iodine green, pentamethylrosanilin chlorid, is produced. **Lyons blue** is triphenylrosanilin chlorid, formed by heating rosanilin chlorid with excess of anilin.

## HYDROCARBONS WITH DIRECTLY UNITED BENZENE NUCLEI.

These hydrocarbons and their derivatives are divided into two classes: 1. Those in which two or more benzene nuclei, each retaining its six C atoms, are attached together by loss of  $\text{H}_2$ . 2. Those in which two or more benzene nuclei are united in such manner that each two possess two atoms of carbon in common, as shown in the formulæ of naphthalene and phenanthrene given below.

of the first class. It is obtained by the action of sodium upon monobromobenzene, or by passing benzene through a red-hot tube. It crystallizes in large plates, fusible at  $70.5$  ( $159.8$  F.); boils at  $254$  ( $489.2$  F.). Diphenyl and its superior homologues, ditoluy, diphenylbenzene, etc., constitute the nuclei of a great number of products of substitution, formed by the replacement of one or more of their H atoms by various radicals and elements, among them being many isomeres produced by differences of orientation.

**Phenanthrene**— $\text{C}_{14}\text{H}_{10}$ —isomeric with anthracene (*q. v.*), may be

considered as a diortho-derivative of diphenyl, or as produced by the fusion of three benzene nuclei, the intermediate one of which has two C atoms in common with each of the extremes :

It crystallizes in brilliant, colorless plates, fusible at  $99^\circ$  ( $210^\circ \text{ F.}$ ), boils at  $340$  ( $644^\circ \text{ F.}$ ), and sublimes readily at lower temperatures. Soluble in hot alcohol, and in cold benzene and ether, the solutions having a distinct blue fluorescence. It accompanies anthracene in the crude product. It is formed synthetically. Oxidizing agents convert it into phenanthroquinone,  $(\text{C}_6\text{H}_4)_2(\text{CO})_2$ .

**Naphthalene**— $\text{C}_{10}\text{H}_8$ —128—is the simplest compound of the second class (see above). It occurs in coal-tar. It has been formed by a synthesis which indicates its constitution. Benzene and ethylene, when heated together, unite to form, first, cinnamene and afterward naphthalene. It is constituted by the fusion of two benzol groups by two C atoms, thus :

It crystallizes in large, brilliant plates ; has a burning taste and a faint aromatic odor ; fuses at  $80^\circ$  ( $176^\circ \text{ F.}$ ) and boils at  $217^\circ$  ( $422.6^\circ \text{ F.}$ ), subliming, however, at lower temperatures ; burns with a bright, smoky flame ; insoluble in water, soluble in alcohol, ether, and essences. It forms substitution compounds with Cl, Br, I,  $\text{HNO}_3$ , and  $\text{H}_2\text{SO}_4$ .

### SUBSTITUTION DERIVATIVES OF NAPHTHALENE.

By the replacement of the hydrogen atoms of naphthalene by other atoms or by radicals, substitution products are obtained somewhat in the same manner as in the case of benzene (see pp. 391-394). In the case of naphthalene, however, the number of isomeres is much greater than with benzene. In the structural

formula of naphthalene the positions 1, 4, 5, 8, although equal to each other, are of different value from the positions 2, 3, 6, 7, also equal to each other, as they are differently disposed with regard to the carbon atoms  $x$  and  $y$ . There exist, therefore, two possible unsubstituted derivatives of naphthalene for a single such derivative of benzene, etc. If the substituted group occupy the approximate positions 1, 4, 5, or 8, it is called an  $\alpha$ -derivative; if it occupy the remote positions 2, 3, 6, or 7, it is a  $\beta$ -derivative.

**Naphthols**— $\text{C}_{10}\text{H}_7\text{OH}$ —of which there are two :

*$\alpha$ -Naphthol* has been obtained by heating phenyl-isocrotonic acid; also by boiling an aqueous solution of diazonaphthalene nitrate with nitrous acid, or by fusing  $\alpha$ -naphthalene-sulphonic acid with  $\text{KHO}$ .

It crystallizes in colorless prisms; fuses at  $94^\circ$  ( $201^\circ.2 \text{ F.}$ ); boils at  $280^\circ$  ( $536^\circ \text{ F.}$ ); is nearly insoluble in water, but soluble in alcohol and in ether, and gives a transient violet color with  $\text{Fe}_2\text{Cl}_6$  and a hypochlorite.

*$\beta$ -Naphthol* = *Isonaphthol*—*Hydronaphthol*—is prepared industrially by fusion of  $\beta$ -naphthalene sulphonate of sodium with  $\text{NaHO}$ , for the manufacture of a number of coloring matters, among which are **Campobello yellow** and **tropeolin**. The commercial product is in reddish-gray, friable, light masses. The pure substance forms colorless, silky, crystalline plates, having a faint, phenol-like odor, and an evanescent, sharp, burning taste. It fuses at  $123^\circ$  ( $253^\circ.4 \text{ F.}$ ), boils at  $286^\circ$  ( $514^\circ.8 \text{ F.}$ ), and is sparingly soluble in water, but readily soluble in alcohol and ether. Its aqueous solutions are not colored violet by  $\text{Fe}_2\text{Cl}_6$ . The pure substance is a valuable antiseptic.

**Naphthylamins**—**Amidonaphthalenes**— $\text{C}_{10}\text{H}_7\text{NH}_2$ .—Two are known, corresponding in constitution to the naphthols. The  $\alpha$  modification is formed by the reduction of  $\alpha$ -nitronaphthalene. It crystallizes in flat needles, fuses at  $50^\circ$  ( $122^\circ \text{ F.}$ ), boils at  $300^\circ$  ( $572^\circ \text{ F.}$ ), insoluble in water, soluble in alcohol and ether. Has a disagreeable and persistent taste.

The  $\beta$ -naphthylamin is produced by the action of ammonia on

$\beta$ -naphthol at  $150-160^\circ$  ( $302-320^\circ$  F.). It forms crystalline plates, fusible at  $112^\circ$  ( $233.6^\circ$  F.), boils at  $294^\circ$  ( $561.2^\circ$  F.); dissolves in hot  $H_2O$ , forming a blue fluorescent solution. Both forms are monacid bases, and form crystalline salts.

Compounds of addition are obtainable from naphthalene as well as products of substitution. They are produced by the freeing of one or more of the double bonds in the positions 1—2; 3—4; 5—6 and 7—8. Among these products is tetrahydro  $\beta$ naphthylamin,  $C_{10}H_7.H.NH_2$ , a very active mydriatic.

### CHINOLIN BASES.

The bases of this group at present known are:

Chinolin.....	$C_9H_7N$	Pentahyrolin.....	$C_{13}H_{15}N$
Lepidin.....	$C_{10}H_9N$	Isolin.....	$C_{14}H_{17}N$
Cryptidin.....	$C_{11}H_{11}N$	Ettidin.....	$C_{15}H_{19}N$
Tetrahyrolin.....	$C_{12}H_{13}N$	Validin.....	$C_{16}H_{21}N$

These bodies, which are closely related to the vegetable alkaloids, bear the same relation to naphthalene that the pyridin bases do to benzene, as will be understood by comparison of the following formulæ:

with those of anilin and picolin given on p. 415. As the molecule of naphthalene may be considered as produced by the fusion of two benzene nuclei, so chinolin may be regarded as resulting from the union of a benzene with a pyridin nucleus.

They are obtained by the destructive distillation of the cinchonin, quinin, and other natural alkaloids, to which they are closely related.

**Chinolin**— $C_9H_7N$ —is a mobile liquid; boils at  $238^\circ$  ( $460.4^\circ$  F.); becomes rapidly colored on contact with air. It has an intensely bitter and acrid taste, and an odor somewhat like that of bitter almonds. It is sparingly soluble in water, readily soluble in alcohol and ether.

Chinolin is the nucleus of a vast number of products of substitution, among which are many isomeres, due to differences in

orientation, according as the substitution occurs in the ortho, meta or para positions in the pyridin group Py (see formula above) or in the 4 or 3 positions in the benzene ring B.

A few of these derivatives are of considerable medical importance.

**Thallin** = *Tetrahydroparachinanisol*— $C_{10}H_{11}NO$ —is a derivative of the paramethyl ether of chinolin. It is met with in the form of sulphate and tartrate in the shape of crystalline powders. The odor of the sulphate is similar to that of anisol (methyl phenate); that of the tartrate to that of coumarin. The taste of both is bitter, acrid, and salty. Both salts are readily soluble in  $H_2O$ , the sulphate the more readily. Solutions of thallin salts assume, even when very dilute, a magnificent emerald-green color with  $Fe_2Cl_6$  solution. A similar color is produced by  $AuCl_3$  and by  $AgNO_3$ .

**Ethylthallin**— $C_{12}H_{13}NO$ —is a derivative of thallin, whose chlorid is hygroscopic; readily forming solutions which are acid in reaction, bitter in taste, and assume a red-brown color with  $Fe_2Cl_6$ .

**Antipyrin** = *Phenyl-dimethyl-pyrazolon*— $C_{11}H_{12}N_2O$ —is obtained by heating phenyl-methyl-pyrazolon with methyl iodid and methyl alcohol in sealed vessels at  $100^\circ$  ( $212^\circ F.$ ); the first-named substance having been previously obtained by the action by acetylacetic ether upon phenyl hydrazin.

It constitutes a voluminous, reddish, crystalline powder; readily soluble in water, ether, alcohol, and chloroform. With nitrous acid, or the nitrites (sp. aeth. nitr.) in the presence of free acids, it forms a green, crystalline, sparingly soluble nitro-derivative which seems to be poisonous.

Its solution with  $Fe_2Cl_6$  is colored deep red-brown, the color being discharged by  $H_2SO_4$ . Nitrous acid colors dilute solutions of antipyrin a bright green, which persists for several days at the ordinary temperature. If the mixture be heated, and a drop of fuming  $HNO_3$  added, the color changes to light red, then blood-red, and the liquid deposits a purple oil on continued heating. Addition of a drop of fuming  $HNO_3$  to a cold concentrated solution of antipyrin produces precipitation of small green crystals.

**Kairin**—*Methyloxychinolin hydrid*— $C_{10}H_{13}NO$ —is more nearly derived from chinolin than the substances previously mentioned. Its chlorid is a crystalline, nearly white, easily soluble powder, whose taste is at once bitter, aromatic, and salty.

Thallin, ethylthallin, antipyrin, and kairin are possessed of antiperiodic and antipyretic properties.

## ANTHRACENE GROUP.

SERIES  $C_nH_{2n-18}$ .

**Anthracene**— $C_{14}H_{10}$ —178—exists as a constituent of coal-tar, and is obtained by expression from the substance remaining in the still after the distillation of naphthalene, etc. The commercial product thus obtained is a yellowish mass containing 50–80 per cent. of anthracene, the purification of which is a matter of considerable difficulty. It has also been obtained synthetically, by the action of the heat on benzyl toluene, and in other ways.

When pure, anthracene crystallizes in rhombic tables having a bluish fluorescence; fusible at 210 (410 F.) and boiling above 360 (680 F.); its best solvents are benzene and carbon disulphid, in which, however, it is only sparingly soluble.

The constitution of anthracene is that of two benzene nuclei united through two of their C atoms by the group  $=CH-CH=$ :

Oxidizing agents convert anthracene into anthraquinone. Reducing agents decompose it into three hydrocarbons,  $C_{14}H_{20}$ ,  $C_7H_{16}$ , and an oily hydrocarbon boiling above 360 (648 F.). Br and Cl attack it violently, I more slowly, forming products of addition.

## DERIVATIVES OF ANTHRACENE.

As may be inferred from the complex molecule of anthracene, the number of possible derivatives of substitution and of addition, including many isomeres, is very great.

**Anthraphenols**— $C_{14}H_9(OH)$ .—Three are known, *a* and *β* anthrol, and anthranol. The two former are produced by the substitution of OH for one of the H atoms *a* or *β* (see formula above) in anthracene, the latter by the substitution of the same group in the positions *x* or *y*.

**Anthraquinone**— $C_{14}H_8\begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix}$ —is formed by oxidation of anthracene. It forms yellow needles, which fuse at 273 (523 F.). It is not easily oxidized, but is converted into anthracene by sufficiently active reducing agents.

Dioxyanthraquinone—Alizarin— $\text{C}_6\text{H}_4 \begin{smallmatrix} \diagup \text{CO} \\ \diagdown \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2 \begin{smallmatrix} \diagup \text{OH} \\ \diagdown \text{OH} \end{smallmatrix}$ —is the red pigment of the madder root (*Rubia tinctoria*). Artificial alizarin has now almost completely displaced the natural product in dyeing. It is obtained by the action of fused  $\text{KHO}$  on many anthracene derivatives, the one generally used being anthraquinone-disulphonic acid,  $\text{C}_{14}\text{H}_8\text{O}_4(\text{SO}_3\text{H})_2$ .

Methylantracene— $\text{C}_{14}\text{H}_{10}$ ,  $\text{CH}_3$ —is obtainable by synthesis, and also by heating chrysophanic acid, emodin, or aloin with zinc-dust.

Chrysophanic Acid—*Parietic Acid*—*Rheic acid*—*Rhein*— $\text{C}_{18}\text{H}_{10}\text{O}_4$ —is a derivative of methylantracene, which exists in the lichens *Parmelia parietina* and *Squamaria elegans*, in senna, and in rhubarb, and obtainable to the extent of 80 per cent. from *Goa powder*=**Chrysarobin**,  $\text{C}_{30}\text{H}_{26}\text{O}_7$ .

Chrysophanic acid crystallizes in golden, orange-yellow, interlaced needles. It is almost tasteless and odorless; fuses at  $162^\circ$  ( $291^\circ \text{ F.}$ ); almost insoluble in cold water, sparingly soluble in hot water, alcohol, and ether, readily soluble in benzene. It forms a red solution with  $\text{H}_2\text{SO}_4$ , from which it is deposited unchanged by water. It also forms red solutions with alkalis. Reducing agents convert it into methylantracene.

Trioxymethylantracene—*Emodin*— $\text{C}_{14}\text{H}_4(\text{CH}_3)(\text{OH})_3\text{O}_2$ —occurs in the bark of *Rhamnus frangula*, and accompanies chrysophanic acid in rhubarb. It crystallizes in long, orange-red prisms which fuse at  $250^\circ$  ( $482^\circ \text{ F.}$ ), and yield methylantracene when heated with zinc-dust.

## TEREBENTHIC SERIES.

In this series are included a number of isomeric hydrocarbons, having the formula  $C_{10}H_{16}$ , or a simple multiple thereof, and their products of derivation. The hydrocarbons are in some cases artificial products, but for the most part exist in nature in the different turpentines, and volatile oils, or essences. When liquid they are called terpenes, when solid camphenes.

**Turpentine—Terebenthina (U. S.)**—is the common *American* turpentine, obtained from incisions in bark of *Pinus palustris* and *P. taeda*, and may be taken as the type of many similar products obtained from other plants. It is a yellowish-white semi-solid, having a balsamic odor, which is divided by distillation into two products. One a liquid, an **elœoptene: oil, or essence of turpentine**; the other a solid, a **stearoptene: rosin, or colophony**.

The liquid product so obtained, oil of turpentine, in the case of the American product consists chiefly of a hydrocarbon,  $C_{10}H_{16}$ , called **australene**, and in the case of the French turpentine of an isomeric body, called **terebenthene**.

These two bodies are obtained from the oils of turpentine by mixing with an alkaline carbonate and subjecting them to fractional distillation in vacuo over the water-bath. The differences between them are principally in their physical properties. Australene is dextrogyrous,  $(\alpha)_D = 17^\circ$ , boils at about  $155^\circ$  ( $311^\circ$  F.). Terebenthene is lævogyrous,  $(\alpha)_D = -40.32$ , boils at  $156.5^\circ$  ( $313.7^\circ$  F.), sp. gr. 0.864 at  $16^\circ$  ( $60.8^\circ$  F.). They are colorless, mobile liquids; have the peculiar odor of turpentine; burn with a smoky, luminous flame. They absorb oxygen rapidly from the air, whether pure or in the commercial essence, becoming thick, and finally gummy. Oxidizing agents, such as  $HNO_3$ , attack them energetically, causing them to ignite and burn suddenly, with separation of a large volume of carbon.  $HCl$  unites with them to form a number of compounds, as do also  $HI$  and  $HBr$ —all the compounds having the odor of camphor. When mixed with  $HNO_3$ , diluted with alcohol, and exposed to the air, they form terpin hydrate.  $Cl$ ,  $Br$  and  $I$  form compounds of substitution or of addition.

Oil of turpentine may be boiled without suffering decomposition, but if heated under pressure at  $250$ – $300^\circ$  ( $482$ – $572^\circ$  F.) the terpene is converted into two products, one liquid, boiling at  $177^\circ$  ( $350.6^\circ$  F.), isomeric with the terpene, called **isoterebenthene**; the other viscous, boiling at about  $400^\circ$  ( $752^\circ$  F.), polymeric with the first,  $C_{20}H_{32}$ , called **metaterebenthene**.

Sulphuric acid acts violently upon oil of turpentine when the two liquids are agitated together, and the latter yields a number of isomeric and polymeric derivatives. After standing 24 hours

the mixture separates into two layers. If the upper layer be distilled at about 250° (482° F.) it yields a mobile liquid, which, when purified by contact with dilute  $\text{H}_2\text{SO}_4$  and then with solution of  $\text{NaHO}$ , and dried and subjected to fractional distillation, may be separated into (1) **Terebene**,  $\text{C}_{10}\text{H}_{16}$ , a colorless, mobile liquid, having a faint odor, optically inactive, boiling at 156° (312.8° F.); (2) **cymene**; (3) a number of polymers of terebenthene, among which is **Colophene**, or **Diterebene**,  $\text{C}_{20}\text{H}_{32}$ , a colorless oil, having a brilliant, indigo-blue fluorescence; boils at 300°–315° (572°–599° F.); sp. gr. 0.91 at 4° (39°.2° F.).

There exist a number of hydrates of the terpenes: **Terpinol**— $2\text{C}_{10}\text{H}_{16}, \text{H}_2\text{O}$ —produced by distilling terpin (see below) with very dilute  $\text{H}_2\text{SO}_4$ , or terpene monochlorhydrate with  $\text{H}_2\text{O}$ , or alcohol. It is a colorless liquid, having the odor of hyacinth, boiling at 168° (234.4° F.); sp. gr. 0.852.

**Terpene hydrate**— $\text{C}_{10}\text{H}_{16}, \text{H}_2\text{O}$ —formed by distilling terpin with  $\text{HCl}$ ; or by allowing French oil of turpentine to remain for some days in contact with alcohol and  $\text{H}_2\text{SO}_4$ . It is an oily liquid, boils at 210°–214° (410°–417°.2° F.), suffering partial decomposition.

**Terpin**— $\text{C}_{10}\text{H}_{16}, 2\text{H}_2\text{O}$ —is formed by the dehydration of terpin hydrate (q. v.). It is crystalline, fusing at 103° (217.4° F.), capable of sublimation, and boils at about 250° (482° F.). It absorbs  $\text{H}_2\text{O}$  eagerly to form terpin hydrate. It behaves like a diatomic alcohol, and is converted into **terebenthene dichlorhydrate**, by gaseous  $\text{HCl}$ , or by  $\text{PCl}_5$ . It is dehydrated by  $\text{P}_2\text{O}_5$ , and converted into terebene and colophene.

**Terpin hydrate**— $\text{C}_{10}\text{H}_{16}, 3\text{H}_2\text{O}$ —formed when oil of turpentine remains for a long time in contact with  $\text{H}_2\text{O}$ , the formation being favored by the presence of a mixture of alcohol and dilute  $\text{HNO}_3$ . It exists in large, colorless, prismatic crystals, odorless, fuses at about 100° (212° F.), sparingly soluble in  $\text{H}_2\text{O}$ , soluble in alcohol and in ether. It readily gives up  $\text{H}_2\text{O}$  in dry air at 100° (212° F.), and is then converted into terpin.

The **Camphenes** are solid, crystalline bodies, having odors resembling that of camphor, formed by the action of the  $\text{Na}$  salts of weak acids, at 200°–220° (392°–428° F.) upon the monochlorhydrates of the corresponding terebenes.

**Isomeres of Terebenthene**.—There exist a great number of bodies, the products of distillation of vegetable substances, which are known as **essences**, **essential oils**, **volatile oils** or **distilled oils**. They resemble each other in being odorous, oily, sparingly soluble in water, more or less soluble in alcohol and ether; colorless or yellowish, inflammable, and prone to become resinous on exposure to air. They are not simple chemical compounds, but

mixtures, and in many of them the principal ingredient is a hydrocarbon, isomeric with terebenthene, and consequently having the composition  $nC_{10}H_{16}$ . Some contain hydrocarbons, others aldehydes, acetones, phenols, and ethers.

Of the numerous other hydrocarbons closely related to terebenthene, but two require further consideration as being the principal constituents of *caoutchouc* and *gutta-percha*.

**Caoutchouc—India-rubber**—is a peculiar substance existing in suspension in the milky juice of quite a number of trees growing in warm climates. It is, when pure, a mixture of two hydrocarbons—*caoutchene*,  $C_{10}H_{16}$ , and *isoprene*,  $C_5H_8$ .

The commercial article is yellowish-brown; sp. gr. 0.919 to 0.942; soft, flexible; almost impermeable, but still capable of acting as a dialyzing membrane when used in sufficiently thin layers. It is insoluble in  $H_2O$  and alcohol, both of which, however, it absorbs by long immersion, the former to the extent of 25 per cent., and the latter of 20 per cent., of its own weight; it is soluble in ether, petroleum, fatty and essential oils; its best solvent is carbon disulphid, either alone, or, better, mixed with 5 parts of absolute alcohol.

It is not acted upon by dilute mineral acids, but is attacked by concentrated  $HNO_3$  and  $H_2SO_4$ , and especially by a mixture of the two. Alkalies tend to render it tougher, although a solution of soda of 40° B. renders it soft after an immersion of a few hours. Cl attacks it after a time, depriving it of its elasticity, and rendering it hard and brittle. When heated it becomes viscous at 145° (293° F.), and fuses at 170–180° (347–356° F.) to a thick liquid, which, on cooling, remains sticky, and only regains its primitive character after a long time. On contact with flame it ignites, burning with a reddish, smoky flame, which is extinguished with difficulty.

The most valuable property of india-rubber, apart from its elasticity, is that which it possesses of entering into combination with S to form what is known as **vulcanized rubber**, which is produced by heating together the normal *caoutchouc* and S to 130–150° (266–302° F.). Ordinary vulcanized rubber differs materially from the natural gum in its properties; its elasticity and flexibility are much increased; it does not harden when exposed to cold; it only fuses at 200° (392° F.); finally, it resists the action of reagents, of solvents, and of the atmosphere much better than does the natural gum.

Frequently rubber tubing is too heavily charged with sulphur for certain chemical uses, in which case it may be desulphurized by boiling with dilute caustic soda solution.

**Hard rubber, vulcanite, or ebonite**, is a hard, tough variety of vulcanized rubber, susceptible of a good polish, and a non-con-

ductor of electricity. It contains 20 to 35 per cent. of S (the ordinary vulcanized rubber contains 7 to 10 per cent.).

**Gutta-percha**—is the concrete juice of *Isouandra gutta*. It is a tough, inelastic, brownish substance, having an odor similar to that of caoutchouc; when warmed it becomes soft and may be moulded, or even cast, so as to assume any form, which it retains on cooling; it may be welded at slightly elevated temperatures, is a good insulating and waterproofing material. It is insoluble in water, alkaline solutions, dilute acids, including hydrofluoric, and in fatty oils; it is soluble in benzene, oil of turpentine, essential oils, chloroform, and especially in carbon disulphid. A solution in chloroform is known as traumaticine, or *Liq. gutta-perchæ* (*U. S.*), and is used to obtain, by its evaporation, a thin film of gutta-percha over parts which it is desired to protect from the air. It is attacked by  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ .

When exposed to air and light, it is gradually changed from the surface inward, assuming a sharp, acid odor, becoming hard and cracked, and even a conductor of electricity.

Gutta-percha seems to be made up of three substances: **Gutta**,  $\text{C}_{20}\text{H}_{22}$ , 75-82 per cent., a white, tough substance, fusing at  $150^\circ$  ( $302^\circ \text{ F.}$ ), soluble in the ordinary solvents of gutta-percha, but insoluble in alcohol and ether. **Albane**,  $\text{C}_{20}\text{H}_{20}\text{O}_2$ , 14-19 per cent., a white, crystalline resin, heavier than water, fusible at  $160^\circ$  ( $320^\circ \text{ F.}$ ); soluble in benzene, essence of turpentine, carbon disulphid, ether, chloroform, and hot absolute alcohol; not attacked by  $\text{HCl}$ . **Fluviale**, 4-6 per cent.,  $\text{C}_{20}\text{H}_{20}\text{O}$ , a yellowish resin, slightly heavier than water, hard and brittle at  $0^\circ$  ( $32^\circ \text{ F.}$ ), soft at  $50^\circ$  ( $122^\circ \text{ F.}$ ), liquid at  $100^\circ$  ( $212^\circ \text{ F.}$ ); soluble in the solvents of gutta-percha.

**Camphors and Resins.**—The camphors are probably aldehydes or alcohols corresponding to hydrocarbons related to terebenthene, although their constitution is still uncertain.

**Common camphor**—*Japan camphor*—*Laurel camphor*—**Campholic aldehyde**—*Camphora* (*U. S.*, *Br.*)— $\text{C}_{15}\text{H}_{10}\text{O}$ —152.—Three modifications are known, which seem to differ from each other only in their action upon polarized light: (1.) **Dextro camphor**—*Camphora officinarum*; obtained from *Laurus camphora*— $[\alpha]_D^{20} = +47.4$ . (2.) **Lævo camphor**, obtained from *Matricaria postlathanium*— $[\alpha]_D^{20} = -47.4$ . (3.) **Inactive camphor**, obtained from the essential oils of rosemary, sage, lavender, and origanum.

The first is the ordinary camphor of the shops. It is a white, translucent, crystalline solid; sp. gr. 0.986-0.996, hot and bitter in taste; aromatic; sparingly soluble in  $\text{H}_2\text{O}$ ; quite soluble in ether, acetic acid, methylic and ethylic alcohols, and the oils; fuses at  $175^\circ$  ( $347^\circ \text{ F.}$ ); boils at  $204^\circ$  ( $399.2^\circ \text{ F.}$ ); sublimes at all temperatures.

It ignites readily and burns with a luminous flame. Cold  $\text{HNO}_3$

dissolves it, and from the solution  $\text{H}_2\text{O}$  precipitates it unchanged. Boiling  $\text{HNO}_3$ , or potassium permanganate, oxidizes it to **dextro camphoric acid**,  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . Concentrated  $\text{H}_2\text{SO}_4$  forms with it a black solution, from which  $\text{H}_2\text{O}$  precipitates *camphene*. Distilled with  $\text{P}_2\text{O}_5$ , it yields *cymene*,  $\text{C}_{10}\text{H}_{14}$ . Alkaline solutions, by long heating under pressure, convert it into **camphic acid**,  $\text{C}_{10}\text{H}_{16}\text{O}_2$ , and **borneol**. Cl attacks it with difficulty. Br unites with it to form an unstable compound, which forms ruby-red crystals, having the composition  $\text{C}_{10}\text{H}_{14}\text{OBr}_2$ . These crystals, when heated to  $80^\circ\text{--}90^\circ$  ( $176^\circ\text{--}194^\circ\text{ F.}$ ), fuse and give off  $\text{HBr}$ , there remaining an amber-colored liquid, which solidifies on cooling, and yields, by recrystallization from boiling alcohol, long, hard, rectangular crystals of **monobromo camphor—Camphora monobromata (U. S.)— $\text{C}_{10}\text{H}_{15}\text{OBr}$** . When vapor of camphor is passed over a mixture of fused potash and lime, heated to  $300^\circ\text{--}400^\circ$  ( $572^\circ\text{--}752^\circ\text{ F.}$ ), it unites directly with the potash to form the K salt of **campholic acid**,  $\text{C}_{10}\text{H}_{15}\text{O}_2$ .

**Borneol—Borneo camphor—Camphol—Camphyl alcohol— $\text{C}_{10}\text{H}_{17}\text{O}$ —154**—is usually obtained from *Dryobalanops camphora*, although it may be obtained from other plants, and even artificially by the hydrogenation of laurel camphor. The product from these different sources is the same chemically, so far as we can determine, but varies, like the modifications of camphor, in its action on polarized light.

It forms small, white, transparent, friable crystals; has an odor which recalls at the same time those of laurel camphor and of pepper; has a hot taste; is insoluble in water, readily soluble in alcohol, ether and acetic acid; fuses at  $198^\circ$  ( $388.4^\circ\text{ F.}$ ), boils at  $212^\circ$  ( $413.6^\circ\text{ F.}$ ).

It is a true alcohol, and enters into double decomposition with acids to form ethers. When heated with  $\text{P}_2\text{O}_5$ , it yields a hydrocarbon, **borneene**,  $\text{C}_{10}\text{H}_{16}$ . Oxidized by  $\text{HNO}_3$ , it is converted into laurel camphor.

**Menthol—Menthyl alcohol— $\text{C}_{10}\text{H}_{20}\text{O}$ —156**—exists in essential oil of peppermint. It crystallizes in colorless prisms; fusible at  $36^\circ$  ( $96.8^\circ\text{ F.}$ ); sparingly soluble in water; readily soluble in alcohol, ether, carbon disulphid, and in acids. Corresponding to it are a series of *menthyl* ethers.

**Eucalyptol— $\text{C}_{12}\text{H}_{20}\text{O}$ —180**—is contained in the leaves of *Eucalyptus globulus*; it is liquid at ordinary temperatures, and boils at  $175^\circ$  ( $347^\circ\text{ F.}$ ); by distillation with phosphoric anhydrid it yields **eucalyptene**,  $\text{C}_{12}\text{H}_{18}$ .

**Resins**—are generally the products of oxidation of the hydrocarbons allied to terebenthene; are amorphous (rarely crystalline); insoluble in water; soluble in alcohol, ether, and essences. Many of them contain acids.

They may be divided into several groups, according to the nature of their constituents: (1.) **Balsams**, which are usually soft or liquid, and are distinguished by containing free *cinnamic* or *benzoic acid* (*q.v.*). The principal members of this group are *benzoin*, *liquidambar*, *Peru balsam*, *styrac*, and *balsam tolu*. (2.) **Oleo-resins** consist of a true resin mixed with an oil, and usually with an oxidized product other than cinnamic or benzoic acid. The principal members of this group are *Burgundy* and *Canada pitch*, *Mecca balsam*, and the resins of *capsicum*, *copaiva*, *cubebs*, *clmi*, *labdanum*, and *lupulin*. (3.) **Gum-resins** are mixtures of true resins and gums. Many of them are possessed of medicinal qualities; *aloes*, *ammoniac*, *asafetida*, *bdellium*, *euphorbium*, *galbanum*, *gamboge*, *guaiac*, *myrrh*, *olibanum*, *opoponax*, and *scammony*. (4.) **True resins** are hard substances obtainable from the members of the three previous classes, and containing neither essences, gums, nor aromatic acids. Such are *colophony* or *rosin*, *copal*, *dammar*, *dragon's blood*, *jalap*, *lar*, *mastic*, and *sandarac*. (5.) **Fossil resins**, such as *amber*, *asphalt*, and *ozocerite*.

## COMPOUNDS OF UNKNOWN CONSTITUTION.

## GLUCOSIDS.

Under this head are classed a number of substances, some of them important medicinal agents, which are the products of vegetable or animal nature. Their characteristic property is that, under the influence of a dilute mineral acid, they yield glucose, phloroglucin or mannite, together with some other substance. Under the supposition that glucose and its congeners are alcohols, it is quite probable that the glucosids are their corresponding ethers.

**Amygdalin**,  $C_{20}H_{27}NO_{11}$ —457—exists in cherry-laurel and in bitter almonds, but not in sweet almonds. Its characteristic reaction is that, in the presence of **emulsin**, which exists in sweet as well as in bitter almonds, and of water, it is decomposed into glucose, benzoic aldehyde, and hydrocyanic acid. The same reaction is brought about by boiling with dilute  $H_2SO_4$  or  $HCl$ . Bitter almonds contain about 2 per cent. of amygdalin.

**Digitalin**.—The pharmaceutical products sold under the above name, and obtained from *digitalis*, are mixtures in varying proportions of several glucosids. **Digitonin**,  $C_{31}H_{52}O_{17}$ , an amorphous, yellowish substance, very soluble in aqueous alcohol. **Digitalin**,  $C_3H_5O_2$ , the principal constituent of the French digitalin, is a colorless, very bitter, crystalline solid, insoluble in water, soluble in alcohol. **Digitalein**, a white, intensely bitter, amorphous solid, very soluble in water, soluble in alcohol. **Digitoxin**,  $C_{31}H_{52}O_7$ , a colorless, crystalline solid, insoluble in water, sparingly soluble in alcohol. It is not a glucosid, and is converted into **toxiresin** by dilute acids.

The **Abstractum digitalis (U. S.)** probably contains all the above, the extraction of the first being more complete with weak alcohol, that of the others with strong alcohol.

**Glycyrrhizin**.—A non-crystallizable, yellowish, pulverulent principle, obtained from liquorice; soluble with difficulty in cold water, soluble in hot water, alcohol, and ether; bitter-sweet in taste. By long boiling with dilute acids it is decomposed into glucose and **glycyrrhetin**,  $C_{18}H_{26}O_4$ .

**Jalapin**— $C_{31}H_{56}O_{16}$ —720—is the active principle of scammony, and exists also to a limited extent in jalap (see below). It is an insipid, colorless, amorphous substance, which is decomposed by dilute acids into glucose and **jalapinol**. The active ingredient of jalap is not, as the name would imply, jalapin, but a resinous substance called **convolvulin**, which is insoluble in ether, odorless,

and insipid. It is not attacked by dilute  $\text{H}_2\text{SO}_4$ , although the concentrated acid dissolves it with a carmine-red color, slowly turning to brown; in alcoholic solution it is decomposed by gaseous  $\text{HCl}$  into glucose and convolvulinic acid.

**Quinovin—Quinovatic acid.**—A bitter principle, possessed of acid functions, obtained from the false bark, known as *Cinchona nova*; it is a glucosid, being decomposed by dilute acids into a sugar resembling mannitan and quinovic acid.

**Salicin—Salicinum (U. S.)— $\text{C}_{13}\text{H}_{11}\text{O}_7$ —286**—occurs in the bark of the willow (*salix*). It is a white, crystalline substance; insoluble in ether, soluble in water and in alcohol; very bitter, its solutions are dextrogyrous,  $[\alpha]_D = +55.8$ . Dilute acids decompose it into glucose and *saligenin* (*q. v.*). Concentrated  $\text{H}_2\text{SO}_4$  colors it red, the color being discharged on the addition of water. When taken into the economy it is converted into salicylic aldehyde and acid, which are eliminated in the urine.

**Santonin—Santonie acid—Santoninum (U. S., Br.)— $\text{C}_{15}\text{H}_{11}\text{O}_5$ —246**.—A glucosid having distinct acid properties; obtained from various species of *Artemisia*. It crystallizes in colorless, rectangular prisms, which turn yellow on exposure to light; odorless and tasteless; insoluble in cold water, sparingly soluble in hot water, alcohol, and ether; its solutions are faintly acid in reaction. Santonin, in solution, gives a chamois-colored precipitate with the ferric salts, and a white precipitate with silver, zinc, and mercurous salts; no precipitate with mercuric salts.

Patients taking santonin pass urine having the appearance of that containing bile, which, when treated with potash, turns cherry-red or crimson, the color being discharged by an acid, and regenerated on neutralization.

**Solanin.**—A glucosid, having basic properties, existing in different plants of the genus *Solanum*. It crystallizes in fine, white, silky needles; having an acrid, bitter taste; insoluble in water, and but sparingly soluble in ether and in alcohol. By the action of hot dilute acids it is decomposed into glucose and a basic substance, solanidin. When not heated, solanin combines with acids to form uncrystallizable salts. Cold concentrated  $\text{H}_2\text{SO}_4$  colors it orange-yellow, and finally forms with it a brown solution;  $\text{HNO}_3$  dissolves it, the solution being at first colorless, afterward rose-pink.

**Strophanthin— $\text{C}_{20}\text{H}_{31}\text{O}_{10}$** —a glucosid from *Strophanthus Kombé*, forms white, crystalline plates, bitter in taste, slightly soluble in water, more soluble in alcohol, insoluble in ether, carbon disulphid and benzene.

**Tannins—Tannic acid— $\text{C}_{14}\text{H}_{10}\text{O}_9$ —322**.—Quite a number of different substances of vegetable origin, principally derived from barks, leaves, and seeds. They are amorphous, soluble in water,

astringent, capable of precipitating albumen, and of forming imputrescible compounds with the gelatinoids. They are, with one possible exception, glucosids.

**Gallo-tannic acid**—*Acidum tannicum* (U. S., Br.)—is the best known of the tannins, and is obtained from nut-galls, *galla* (U. S., Br.), which are excrescences produced upon oak trees by the puncture of minute insects. It appears as a yellowish, amorphous, odorless, friable mass; has an astringent taste; very soluble in water, less so in alcohol, almost insoluble in ether; its solutions are acid in reaction, and on contact with animal tissues give up the dissolved tannin, which becomes fixed by the tissue to form a tough, insoluble, and non-putrescible material (leather).

A freshly prepared solution of pure gallo-tannic acid gives a dark blue precipitate with ferric salts, but not with ferrous salts. If, however, the solution have been exposed to the air, it is altered by oxidation, and gives, with ferrous salts, a black color (in whose production gallic acid probably plays an important part), which is the coloring material of ordinary writing-ink.

**Caffetannic acid**—exists in saline combination in coffee and in Paraguay tea. It colors the ferric salts green, and does not affect the ferrous salts, except in the presence of ammonia; it precipitates the salts of quinin and of cinchonin, but does not precipitate tartar emetic or gelatin. It is a glucosid, being decomposed by suitable means into *caffaic acid* and *mannitan*.

**Cachoutannic acid**—obtained from catechu, is soluble in water, alcohol, and ether. Its solutions precipitate gelatin, but not tartar emetic; they color the ferric salts grayish-green.

**Morintannic acid**—*Maclurin*—a yellow, crystalline substance, obtained from fustic; more soluble in alcohol than in water. Its solutions precipitate green with ferroso-ferric solutions; yellow with lead acetate; brown with tartar emetic; yellowish-brown with cupric sulphate. It is decomposable into *phloroglucin* and *protocatechuic acid*.

**Quercitannic acid**—is the active tanning principle of oak-bark; it differs from gallo-tannic acid in not being capable of conversion into gallic acid, and in not furnishing pyrogallol on dry distillation. It forms a violet-black precipitate with ferric salts. The tannin existing in black tea seems to be quercitannic acid.

**Quinotannic acid**—a tannin existing in cinchona barks, probably in combination with the alkaloids. It is a light yellow substance; soluble in water, alcohol, and ether; its taste is astringent, but not bitter. Dilute  $H_2SO_4$  decomposes it, at a boiling temperature, into glucose and a red substance—*quinova red*.

## ALKALOIDS.

The alkaloids are organic, nitrogenized substances, alkaline in reaction, and capable of combining with acids to form salts in the same way as does ammonia. They are also known as vegetable or organic bases or alkalies, and are probably amines of complex constitution. The similarity between the relation of the free alkaloids to their salts and that of ammonia to the ammoniacal salts is shown in the following equations:

**Classification.**—The natural alkaloids are temporarily arranged in two groups:

(1.) Those which are liquid and volatile, and consist of C, H and N. The synthesis of one of their number shows that they are true amines.

(2.) Those which are solid, crystalline, volatile with difficulty, if at all, and consist of C, H, N and O. No representative of this class has yet been obtained by synthesis.

**General Physical Characters.**—As a rule they are insoluble, or nearly so, in water; more soluble in alcohol, chloroform, petroleum-ether, and benzene. Their salts are, for the most part, soluble in water and insoluble or sparingly soluble in petroleum-ether, benzene, ether, chloroform, and amyl alcohol. All exert a rotary action on polarized light:

Quinin .....	$[\alpha] = -126^\circ.7$	Codein.....	$[\alpha] = -118^\circ.2$
Quinidin .....	$[\alpha] = +250^\circ.75$	Narcein.....	$[\alpha] = -6^\circ.7$
Cinchonin .....	$[\alpha] = -190^\circ.4$	Strychnin.....	$[\alpha] = -132^\circ.07$
Cinchonidin....	$[\alpha] = -144^\circ.61$	Brucin.....	$[\alpha] = -61^\circ.27$
Morphin... ..	$[\alpha] = -88^\circ.4$	Nicotin.....	$[\alpha] = -93^\circ.5$
Narcotin.....	$[\alpha] = -103^\circ.5$		

Generally, combination with an acid diminishes their rotary power; with quinin the reverse is the case. Free narcotin is levogyrous; its salts are dextrogyrous. They are all bitter in taste.

**General Chemical Reactions.**—*Potash, soda, ammonia, lime, baryta, and magnesia* precipitate the alkaloids from solutions of their salts.

*Phosphomolybdic acid* forms a precipitate which is bright yellow, with anilin, morphin, veratrin, aconitin, emetin, atropin, hyoseyamin, thein, theobromin, conifin, and nicotin; brownish-

yellow with narcotin, codein, and piperin; yellowish-white with quinin, cinchonin and strychnin; yolk-yellow with brucin.

The reagent is prepared as follows: Ammonium molybdate is dissolved in  $H_2O$ , the solution filtered, and a quantity of hydrodisodic phosphate  $\frac{1}{5}$  in weight of the molybdate used is added, and then  $HNO_3$  to strong acid reaction. The mixture is warmed; set aside for a day; the yellow ppt. collected on a filter; washed with  $H_2O$  acidulated with  $HNO_3$ ; and while still moist transferred to a porcelain capsule, to which the liquid obtained by exhausting the remainder on the filter with  $NH_4HO$  is added. The fluid is warmed and gradually treated with pulverized sodium carbonate until a colorless solution is obtained. This is evaporated to dryness; a small quantity of sodium nitrate is added, and the whole gradually heated to quiet fusion and until all  $NH_3$  is expelled. The residue is dissolved in warm  $H_2O$  (1 to 10), acidulated with  $HNO_3$ , and decanted.

To use the reagent, a drop of the suspected liquid is placed on a glass plate with a black background, and near it a drop of the reagent; and the two drops are made to mix slowly by a pointed glass rod.

*Potassium iodhydrargyrate* gives a yellowish precipitate with alkaloidal solutions which are acid, neutral, or faintly alkaline in reaction.

The reagent is obtained by dissolving 13.546 grams of mercuric chlorid and 49.8 grams of potassium iodid in a litre of water.

The solution may be used for quantitative determinations. The reagent is added from a burette to the solution of alkaloid until a drop, filtered from the solution which is being tested, and placed upon a black surface, gives no precipitate with a drop of the reagent. Each c.c. of reagent used indicates the presence in the volume of liquid tested of the following quantities of alkaloids, in grams:

Aconitin ..	0.0267	Morphin .....	0.0200
Atropin .....	0.0145	Coniïn ..	0.00416
Narcotin. .	0.0213	Nicotin .....	0.00405
Strychnin .....	0.0167	Quinin .....	0.0108
Brucin.....	0.0233	Cinchonin .....	0.0102
Veratrin .....	0.0269	Quinidin .....	0.0120

Of course, the process can be used only in a solution containing a single alkaloid.

**Separation of Alkaloids from Organic Mixtures and from Each Other.**—One of the most difficult of the toxicologist's tasks is the separation from a mixture of organic material (contents of stomach, viscera) of an alkaloid in such a state of purity as to render its identification perfect. The difficulty is the greater if the amount present be small, as is usually the case; and if the search be not confined to a single alkaloid, as frequently occurs. Some of these substances, as strychnin, are detectable with much greater facility and certainty than others.

Of the processes hitherto suggested, the best is that of Dragendorff, devised for the detection of any alkaloid or poisonous organic principle present in the substances examined. It is very exhaustive, and well adapted to cases frequently arising in chemico-legal practice; but, on the other hand, is too intricate to be serviceable to the general practitioner.

An abridgement of this process may be of use to detect the presence of the more commonly used alkaloids in a mixture of organic material. *The physician should, however, bear in mind that, in cases liable to give rise to legal proceedings, these may become seriously complicated by the analysis of any parts of the body, dejecta, or suspected articles of food, etc., by any process open to attack by the most searching cross examination.*

The substances to be examined are reduced to a fine state of subdivision, and are digested for an hour or more in water acidulated with  $\text{H}_2\text{SO}_4$ , at a temperature of  $40^\circ$  to  $50^\circ$  ( $104^\circ$ – $122^\circ$  F.); this is repeated three times, the liquid being filtered and the solid material expressed. The united extracts are evaporated at the temperature of the water-bath to a *thin* syrup; this is mixed with three or four volumes of alcohol, the mixture kept at about  $35^\circ$  ( $95^\circ$  F.) for 24 hours, cooled well and filtered; the residue being washed with seventy per cent. alcohol. The alcohol is distilled from the filtrate, and the watery residue diluted with  $\text{H}_2\text{O}$  and filtered.

The filtrate so obtained contains the sulphates of the alkaloids, and from it the alkaloids themselves are separated by the following steps:

A. The acid watery liquid is shaken with freshly rectified petroleum-ether (which should boil at about  $65^\circ$ – $70^\circ$  ( $149^\circ$ – $158^\circ$  F.)), and should be used with caution, as it is very inflammable; after several agitations the ether layer is allowed to separate and is removed; this treatment is repeated so long as the ether dissolves anything. The residue obtained by the evaporation of the ether—*Residue I.*—is mostly composed of coloring matters, etc., which it is desirable to remove.

B. The same treatment of the watery liquid is repeated with benzene, which on evaporation yields *Residue II.*, which is, if crystalline, to be tested for cantharidin, santonin, and digitalin (*q.v.*); if amorphous, for elaterin and colchicin.

C. The acid, aqueous fluid is then treated in the same way with chloroform to obtain *Residue III.*, which is examined for cinchonin, digitalin, and picrotoxin by the proper tests.

D. The watery fluid, after one more shaking with petroleum-ether and removal of the ethereal layer, is rendered alkaline with ammonium hydrate and shaken with petroleum-ether at  $40^\circ$  ( $104^\circ$  F.), the ethereal layer being removed as quickly as possible while still warm; this is repeated two or three times, and repeated with *cold* petroleum-ether, which is removed after a time. The warm ethereal layers yield *Residue IV. a*; the cold ones *Residue IV. b*. The former is tested for strychnin, quinin, brucin, veratrin; the latter for coniin and nicotin.

E. The alkaline, watery fluid is shaken with benzene, which, on evaporation, yields *Residue V.*, which may contain strychnin.

brucin, quinin, cinchonin, atropin, hyoseyamin, physostigmin, aconitin, codein, thebain, and narcein.

F. A similar treatment with chloroform yields *Residue VI.*, which may contain a trace of morphin.

G. The alkaline liquid is then shaken with amyl alcohol, which is separated and evaporated; *Residue VII.* is tested for morphin, solanin, and salicin.

H. Finally, the watery liquid is itself evaporated with pounded glass, the residue extracted with chloroform, and *Residue VIII.*, left by the evaporation of the chloroform, tested for curarin.

### Volatile Alkaloids.

**Coniin—Conicin—Cicutin— $C_8H_{15}N$ —125**—is obtained from *Conium maculatum*, in which it is accompanied by two other alkaloids, methyl-coniin,  $C_8H_{14}N(CH_3)$ , and conhydrin,  $C_9H_{17}NO$ —the former a volatile liquid, the second a crystalline solid.

Coniin is a colorless, oily liquid; has an acrid taste and a disagreeable penetrating odor; sp. gr. 0.878; can be distilled when protected from air; boils at  $212^\circ$  ( $413.6^\circ F.$ ); exposed to air it resinifies; it is very sparingly soluble in water, but is more soluble in cold than in hot water; soluble in all proportions in alcohol, soluble in six volumes of ether, very soluble in fixed and volatile oils.

The vapor which it gives off at ordinary temperatures forms a white cloud when it comes in contact with a glass rod moistened with HCl, as does  $NH_3$ . It forms salts which crystallize with difficulty. Cl and Br combine with it to form crystallizable compounds; I in alcoholic solution forms a brown precipitate in alcoholic solutions of coniin, which is soluble without color in an excess. Oxidizing agents attack it with production of butyric acid (see below). The iodids of ethyl and methyl combine with it to form iodids of ethyl- and methyl-conium. It has been obtained synthetically by first allowing butyric aldehyde and an alcoholic solution of ammonia to remain some months in contact at  $30^\circ$  ( $86^\circ F.$ ), when dibutyraldin is formed:

The dibutyraldin thus obtained is then heated under pressure to  $150^\circ$ – $180^\circ$  ( $302^\circ$ – $356^\circ F.$ ), when it loses water:

A synthesis which, in connection with the decompositions of coniin, shows its rational formula to be  $(C_4H_7) \left. \begin{array}{c} \phantom{C_4H_7} \\ H \end{array} \right\} N$ .

**ANALYTICAL CHARACTERS.**—(1.) With dry HCl gas it turns reddish-purple, and then dark blue. (2.) Aqueous HCl of sp. gr. 1.12 evaporated from *coniïn* leaves a green-blue, crystalline mass. (3.) With iodic acid a white ppt. from alcoholic solutions. (4.) With  $\text{H}_2\text{SO}_4$  and evaporation of the acid: a red color, changing to green, and an odor of butyric acid. (5.) When mixed with commercial nitrobenzene a fine blue color is produced, changing to red and yellow.

**Nicotin**— $\text{C}_{10}\text{H}_{14}\text{N}_2$ —162—exists in tobacco in the proportion of 2-8 per cent.

It is a colorless, oily liquid, which turns brown on exposure to light and air; has a burning, caustic taste and a disagreeable, penetrating odor; it distils at  $250^\circ$  ( $392^\circ \text{F.}$ ); it burns with a luminous flame; sp. gr. 1.027 at  $15^\circ$  ( $59^\circ \text{F.}$ ); it is very soluble in water, alcohol, the fatty oils, and ether; the last-named fluid removes it from its aqueous solution when the two are shaken together; it absorbs water, rapidly from moist air. Its salts are deliquescent, and crystallize with difficulty.

**ANALYTICAL CHARACTERS.**—(1.) Its ethereal solution, added to an ethereal solution of iodine, separates a reddish-brown, resinoid oil, which gradually becomes crystalline. (2.) With HCl, a violet color. (3.) With  $\text{HNO}_3$ , an orange color.

Both *nicotin* and *coniïn* are actively poisonous, producing death by asphyxia, sometimes as rapidly as prussic acid.

**Sparteïn**— $\text{C}_{15}\text{H}_{25}\text{N}_2$ —a colorless oil, whose odor resembles that of anilin; extremely bitter in taste; sparingly soluble in water, forming an alkaline solution. On exposure to air becomes brown and resinous.

### Fixed Alkaloids.

These are much more numerous than those which are volatile, and form the active principles of a great number of poisonous plants. As we are yet in the dark as to the constitution of these bodies, the classification which we adopt is the temporary one, based upon the botanic character of the plants from which they are derived.

**Opium Alkaloids.**—Opium is the inspissated juice of the capsules of the poppy. It is of exceedingly complex composition, and contains, besides a neutral body called *meconin* (probably a poly-atomic alcohol,  $\text{C}_{10}\text{H}_{15}\text{O}_4$ ), a peculiar acid, *meconic acid* (*q.v.*), lactic acid, gum, albumen, wax, and a volatile matter—no less than eighteen different alkaloids, one or two of which, however, are probably formed during the process of extraction, and do not pre-exist in opium.

The following is a list of the constituents of opium, those marked \* being of medical interest:

Name.	Formula.	Per Cent. in Smyrna Opium.	Per Cent. in Constanti-nople Opium
* Meconic acid .....	$C_7H_4O_7$	4.70	4.38
Lactic acid .....	$C_3H_5O_3$	1.25	....
Meconin .....	$C_{10}H_{10}O_4$	0.08	0.30
* Morphin .....	$C_{17}H_{19}NO_3$	10.30	4.50
Pseudomorphin .....	$C_{17}H_{19}NO_4$	....	....
Hydrocotarnin .....	$C_{12}H_{15}NO_3$	....	....
* Codein .....	$C_{18}H_{21}NO_3$	0.25	1.52
* Thebain .....	$C_{19}H_{21}NO_3$	0.15	....
Protopin .....	$C_{20}H_{19}NO_5$	....	....
Rhæadin .....	$C_{20}H_{21}NO_5$	....	....
Codamin .....	$C_{20}H_{25}NO_4$	....	....
Laudanin .....	$C_{20}H_{25}NO_4$	....	....
Papaverin .....	$C_{21}H_{21}NO_4$	1.00	....
Opianin .....	$C_{21}H_{21}NO_7$	....	....
Meconidin .....	$C_{21}H_{23}NO_4$	....	....
Cryptopin .....	$C_{21}H_{23}NO_5$	....	....
Laudanosin .....	$C_{21}H_{27}NO_4$	....	....
* Narcotin .....	$C_{22}H_{23}NO_7$	1.30	3.47
Lanthopin .....	$C_{23}H_{25}NO_4$	....	....
* Narcein .....	$C_{23}H_{29}NO_5$	0.71	0.42
Porphyroxin .....	.....	....	....

**Morphin—Morphina (U. S.)**— $C_{17}H_{19}NO_3 + Aq$ —285+18—crystallizes in colorless prisms; odorless, but very bitter; it fuses at 120 (248 F.), losing its Aq. More strongly heated, it swells up, becomes carbonized, and finally burns. It is soluble in 1,000 pts. of cold water, in 100 pts. of boiling water; in 20 pts. of alcohol of 0.82, and in 13 pts. of boiling alcohol of the same strength; in 390 pts. of cold amyl alcohol, much more soluble in the same liquid warm; almost insoluble in aqueous ether; rather more soluble in alcoholic ether; almost insoluble in benzene; soluble in 60 pts. of chloroform. All the solvents dissolve morphin more readily and more copiously when it is freshly precipitated from solutions of its salts than when it has assumed the crystalline form.

Morphin combines with acids to form crystallizable salts, of which the chlorid, sulphate, and acetate are used in medicine. If morphin be heated for some hours with excess of HCl, under pressure, to 150 (302° F.), it loses water, and is converted into a new base—**apomorphin**,  $C_{17}H_{17}NO_2$ .

By the action of  $H_2SO_4$  on morphin at 100°, two amorphous, basic products of condensation, **trimorphin** and **tetramorphin**, are produced.

By heating together acetic anhydrid and morphin, three modifications,  $\alpha$ ,  $\beta$ ,  $\gamma$ , of **acetyl-morphin**,  $C_{17}H_{17}(C_2H_3O)NO_2$ , are formed.

Similarly substituted butyryl-, benzoyl-, succinyl-, camphoryl-, methyl-, and ethyl-morphin are also known.

Although the synthesis of morphin has not yet been accomplished, enough is known of its constitution to indicate that it contains the phenolic group (OH), and that it is a derivative of phenanthrene (see p. 423).

The salts of morphin are crystalline. The *acetate*—**Morphinæ acetat**, U. S.—**Morphiæ acetat**, Br.—is a white, crystalline powder, soluble in 12 parts of water, which decomposes on exposure to air, with loss of acetic acid. The *chlorid*—**Morphinæ hydrochlorat**, U. S.—is less soluble, but more permanent than the acetate. The *sulphate*—**Morphinæ sulphat**, U. S.—**Morphiæ sulphat**, Br.—is the form in which morphin is the most frequently used in medicine. It is a very light, crystalline, feathery powder; odorless, bitter, and neutral in reaction. It dissolves in 24 parts of water. Its solutions deposit morphin as a white precipitate on addition of an alkali. The crystals contain 5 Aq. which they lose at 130° (266° F.).

ANALYTICAL CHARACTERS.—(1.) It is colored red, changing to yellow, by  $\text{HNO}_3$ . (2.) Cold concentrated  $\text{H}_2\text{SO}_4$  dissolves it, forming a colorless solution, which after 24 hours turns pink on addition of a trace of  $\text{HNO}_3$ ; and the fluid when warmed, cooled, and diluted with  $\text{H}_2\text{O}$ , turns deep mahogany-brown on the addition of a splinter of potassium dichromate. (3.) A mixture of morphin and cane-sugar (1 to 4) added to concentrated  $\text{H}_2\text{SO}_4$  gives a dark red color, which is intensified by a drop of bromin-water. (4.) If iodic acid solution and a drop of chloroform be added to morphin, free iodin is liberated, which colors the chloroform violet. If now dilute  $\text{NH}_4\text{HO}$  be floated on the surface of the liquid, a dark brownish zone is formed. (5.) A neutral solution of a morphin salt gives a blue color with neutral solution of ferric chlorid. (6.) A solution of molybdic acid in  $\text{H}_2\text{SO}_4$  (Fröhde's reagent) gives with morphin a violet color, changing to blue, dirty green, and faint pink. Water discharges the color. (7.) Solution of morphin acetate produces a gray ppt. when warmed with ammoniacal silver nitrate solution; and the filtrate turns red or pink with  $\text{HNO}_3$ . (8.) Auric chlorid gives a yellow ppt., turning violet-blue, with solutions of morphin salts. (9.) Add solution of  $\text{Fe}_2\text{Cl}_6$  (2-16) to solution of potassium ferrieyanid (the mixture must not assume a blue color), add morphin solution—a deep blue color. (10.) Heat morphin with concentrated  $\text{H}_2\text{SO}_4$  to 200° (392° F.) until green-black; add a drop of the liquid cautiously to water; the solution turns blue. Shake a portion with ether; the ether turns purple. Shake another portion with chloroform; the chloroform turns blue. (11.) Warm the solid alkaloid with concentrated  $\text{H}_2\text{SO}_4$ ; add cautiously a few drops of alcoholic

solution of KHO (30%); a yellow color is produced, changing to dirty red, then steel-blue, and sky-blue, and, with a further quantity of KHO solution, cherry-red.

**Codein—Codeina** (U. S.)— $C_{17}H_{21}NO_3 + Aq - 299 + 18$ —crystallizes in large rhombic prisms, or from ether, without Aq, in octahedra; bitter; soluble in 80 pts. cold water; 17 pts. boiling water; very soluble in alcohol, ether, chloroform, benzene; almost insoluble in petroleum-ether.

**ANALYTICAL CHARACTERS.**—(1.) Cold concentrated  $H_2SO_4$  forms with it a colorless solution, which turns blue after some days, or when warmed. (2.) Fröhde's reagent dissolves it with a dirty green color, which after a time turns blue. (3.) Chlorin-water forms with it a colorless solution, which turns yellowish-red with  $NH_4HO$ .

**Narcein— $C_{23}H_{29}NO_9 + 2Aq - 463 + 36$** —crystallizes in bitter, prismatic needles; sparingly soluble in water, alcohol, and amyl alcohol; insoluble in ether, benzene, and petroleum-ether.

**ANALYTICAL CHARACTERS.**—(1.) Concentrated  $H_2SO_4$  dissolves it with a gray-brown color, which changes to red, slowly at ordinary temperatures, rapidly when heated. (2.) Fröhde's reagent colors it dark olive-green, passing to red after a time, or when heated. (3.) Iodin solution colors it blue-violet, like starch.

**Narcotin— $C_{22}H_{23}NO_7 - 413$** —crystallizes in transparent prisms, almost insoluble in water and in petroleum-ether; soluble in alcohol, ether, benzene, and chloroform. Its salts are mostly uncrystallizable, unstable, and readily soluble in water and alcohol.

**ANALYTICAL CHARACTERS.**—(1.) Concentrated  $H_2SO_4$  forms with it a solution, at first colorless, in a few moments yellow, and after a day or two, red. (2.) Its solution in dilute  $H_2SO_4$ , if gradually evaporated until the acid volatilizes, turns orange-red, bluish-violet and reddish-violet. (3.) Fröhde's reagent dissolves it with a greenish color, passing to cherry-red.

**Thebain—Paramorphin— $C_{19}H_{21}NO_5 - 311$** —crystallizes in white plates; tasteless when pure; insoluble in water; soluble in alcohol, ether and benzene.

**ANALYTICAL CHARACTERS.**—(1.) With concentrated  $H_2SO_4$  an immediate bright red color, turning to yellowish-red. (2.) Its solution in chlorin-water turns reddish-brown with  $NH_4HO$ . (3.) With Fröhde's reagent same as 1.

**Apomorphin— $C_{17}H_{17}NO_2$** —is used hypodermically as an emetic in the shape of the chlorid, **Apomorphinæ hydrochloras**, U. S. It is obtained by sealing morphin with an excess of strong HCl in a thick glass tube, and heating the whole to 140 (252 F.) for two to three hours. It is obtained also by the same process from codein. The free alkaloid is a white, amorphous solid, difficultly soluble in water. The chlorid forms colorless, shining crystals,

which have a tendency to assume a green color on exposure to light and air. It is odorless, bitter and neutral; soluble in 6.8 parts of cold water.

**Toxicology of Opium and its Derivatives.**—Opium, its preparations and the alkaloids obtained from it, are all active poisons. They produce drowsiness, stupor, slow and stertorous respiration, contraction of the pupils, small and irregular pulse, coma, and death. The symptoms set in from 10 minutes to 3 hours, sometimes immediately, sometimes only after 18 hours. Death has occurred in from 45 minutes to 3 days, usually in 5 to 18 hours. After 24 hours the prognosis is favorable. Death has been caused in an adult by one-half grain of acetate of morphia, while 30 grains a day have been taken by those accustomed to its use without ill effects.

The alkaloids of opium have not the same action. In soporific action, beginning with the most powerful, they rank thus: Narceïn, morphin, codeïn; in tetanizing action: thebaïn, papaverin, narcotin, codeïn, morphin; in toxic action: thebaïn, codeïn, papaverin, narceïn, morphin, narcotin.

The treatment should consist in the removal of unabsorbed poison from the stomach by emesis and the stomach-pump, and washing out of the stomach after injection into it of powdered charcoal in suspension, or tea or coffee infusion. Cold affusions should be used, and the patient should be kept awake.

After death the reactions for meconic acid and narcotin permit of distinguishing whether the poisoning was by opium or its preparations, or by morphin.

**Cinchona Alkaloids.**—Although by no means so complex as opium, cinchona bark contains a great number of substances: *quinin*, *cinchonin*, *quinidin*, *cinchonidin*, *aricin*; *quinic*, *quinotannic*, and *quinovic acids*; *cinchona red*, etc. Of these the most important are quinin and cinchonin.

**Quinin—Quinina** (U. S.)— $C_{20}H_{21}N_2O_2 + n Aq - 324 + n18$ —exists in the bark of a variety of trees of the genera *Cinchona* and *China*, indigenous in the mountainous regions of the north of South America, which vary considerably in their richness in this alkaloid, and consequently in value; the best samples of calisaya bark contain from 30 to 32 parts per 1,000 of the sulphate; the poorer grades 4 to 20 parts per 1,000; inferior grades of bark contain from mere traces to 6 parts per 1,000.

It is known in three different states of hydration, with 1, 2, and 3 Aq. and anhydrous. The anhydrous form is an amorphous, resinous substance, obtained by evaporation of solutions in anhydrous alcohol or ether. The first hydrate is obtained in crystals by exposing to air recently precipitated and well-washed quinin.

The second by precipitating by ammonia a solution of quinin sulphate, in which H has been previously liberated by the action of Zn upon  $\text{H}_2\text{SO}_4$ ; it is a greenish, resinous body, which loses  $\text{H}_2\text{O}$  at  $150^\circ$  ( $302^\circ \text{F.}$ ). The third, that to which the following remarks apply, is formed by precipitating solution of quinin salts with ammonia.

It crystallizes in hexagonal prisms; very bitter; fuses at  $57$  ( $134.6 \text{ F.}$ ); loses Aq at  $100^\circ$  ( $212 \text{ F.}$ ) and the remainder at  $125$  ( $257 \text{ F.}$ ); becomes colored, swells up, and, finally, burns with a smoky flame. It does not sublime. It dissolves in 2,200 pts. of cold  $\text{H}_2\text{O}$ , in 760 of hot  $\text{H}_2\text{O}$ ; very soluble in alcohol and chloroform; soluble in amyl alcohol, benzene, fatty and essential oils, and ether. Its alcoholic solution is powerfully laxogyrus,  $[\alpha]_D = -270.7$  at  $18^\circ$  ( $64.4 \text{ F.}$ ), which is diminished by increase of temperature, but increased by the presence of acids.

ANALYTICAL CHARACTERS.—(1.) Dilute  $\text{H}_2\text{SO}_4$  dissolves quinin in colorless but fluorescent solution (see below). (2.) Solutions of quinin salts turn green when treated with Cl and then with  $\text{NH}_3$ . (3.) Cl passed through  $\text{H}_2\text{O}$  holding quinin in suspension forms a red solution. (4.) Solution of quinin treated with Cl water and then with fragments of potassium ferrocyanid becomes pink, passing to red.

SULPHATE—*Disulphate*—**Quininæ sulphas (U. S.)**—**Quiniæ sulphas (Br.)**— $\text{SO}_4(\text{C}_{20}\text{H}_{25}\text{N}_2\text{O}_2)_2 + 7\text{Aq} - 746 + 126$ —crystallizes in prismatic needles; very light; intensely bitter; phosphorescent at  $100^\circ$  ( $212 \text{ F.}$ ); fuses readily; loses its Aq at  $120^\circ$  ( $248 \text{ F.}$ ), turns red, and finally carbonizes; effloresces in air, losing 6 Aq; soluble in 740 pts.  $\text{H}_2\text{O}$  at  $13^\circ$  ( $55.4 \text{ F.}$ ), in 30 pts. boiling  $\text{H}_2\text{O}$ , and 60 pts. alcohol. Its solution with alcoholic solution of I deposits brilliant green crystals of iodoquinin sulphate.

HYDROSULPHATE—**Quininæ bisulphas (U. S.)**— $\text{SO}_4\text{H}(\text{C}_{20}\text{H}_{25}\text{N}_2\text{O}_2) + 7\text{Aq} - 422 + 126$ —is formed when the sulphate is dissolved in excess of dilute  $\text{H}_2\text{SO}_4$ . It crystallizes in long, silky needles, or in short, rectangular prisms; soluble in 10 pts.  $\text{H}_2\text{O}$  at  $15^\circ$  ( $59 \text{ F.}$ ). Its solutions exhibit a marked fluorescence, being colorless, but showing a fine pale blue color when illuminated by a bright light against a dark background.

IMPURITIES.—Quinin sulphate should respond to the following tests: (1.) When 1 gram (15.4 grains) is shaken in a test-tube with 15 c.c. (4 fl.  $\bar{\text{z}}$ ) of ether, and 2 c.c. (32  $\bar{\text{m}}$ ) of  $\text{NH}_4\text{HO}$ : the liquids should separate into two clear layers, without any milky zone between them (cinchonin). (2.) Dissolved in hot  $\text{H}_2\text{O}$ , the solution precipitated with an alkaline oxalate, the filtrate should not ppt. with  $\text{NH}_4\text{HO}$  (quinidin). (3.) It should dissolve completely in dilute  $\text{H}_2\text{SO}_4$  (fats, resins). (4.) It should dissolve completely in boiling, dilute alcohol (gum, starch, salts). (5.) It should not

blacken with  $\text{H}_2\text{SO}_4$  (cane-sugar). (6.) It should not turn red or yellow with  $\text{H}_2\text{SO}_4$  (salicin and phlorizin). (7.) It should leave no residue when burnt on platinum foil (mineral substances).

By the action of alkaline hydrates upon quinin, formic acid, chinolin (see p. 426), and pyridin bases (see p. 415) are produced.

Concentrated  $\text{HCl}$  at  $140^\circ$ – $150^\circ$  ( $284^\circ$ – $302^\circ$  F.) decomposes quinin, with separation of methyl chlorid and formation of apoquinin,  $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}_2$ , an amorphous base.

Oxidizing agents produce from quinin oxalic acid and acids related to pyridin, notably pyridindicarboxic or cinchomeronic acid,  $\text{C}_6\text{H}_4\text{N}_2\text{COOH}_2$ , which are also formed by oxidation of cinchonin.

Although cinchonin (see below) differs from quinin in composition by  $+\text{O}$ , and although the decompositions of the two bases show them both to be related to the chinolin and pyridin bases, attempts to convert cinchonin into quinin have resulted only in the formation of other products, among which is an isomere of quinin, **oxycinchonin**.

**Methylquinin**,  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{CH}_3$ , is a base which has a curare-like action.

**Cinchonin—Cinchonina** (U. S.)— $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}$ —294—occurs in Peruvian bark in from 2 to 30 pts. per 1,000. It crystallizes without Aq in colorless prisms; fuses at  $150^\circ$  ( $302^\circ$  F.); soluble in 3,810 pts.  $\text{H}_2\text{O}$  at  $10^\circ$  ( $50^\circ$  F.), in 2,500 pts. boiling  $\text{H}_2\text{O}$ ; in 140 pts. alcohol and in 40 pts. chloroform. The salts of cinchonin resemble those of quinin in composition; are quite soluble in  $\text{H}_2\text{O}$  and alcohol; are not fluorescent; permanent in air; phosphorescent at  $100^\circ$  ( $212^\circ$  F.).

**Quinidin and Quinicin**—are bases isomeric with quinin; the former occurring in cinchona bark, and distinguishable from quinin by its strong dextrorotary power; the second a product of the action of heat on quinin, not existing in cinchona.

**Cinchonidin**—a base, isomeric with cinchonin, occurring in certain varieties of bark; levogyrous. At  $130^\circ$  ( $266^\circ$  F.)  $\text{H}_2\text{SO}_4$  converts it into another isomere, **cinchoninicin**.

**Caffein—Thein—Guaranin—Caffeina** (U. S.)— $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$  + Aq—194+18—exists in coffee, tea, Paraguay tea, and other plants. It crystallizes in long, silky needles; faintly bitter; soluble in 75 pts.  $\text{H}_2\text{O}$  at  $15^\circ$  ( $59^\circ$  F.); less soluble in alcohol and ether. Hot fuming  $\text{HNO}_3$  converts it into a yellow liquid, which after evaporation turns purple with  $\text{NH}_4\text{HO}$ .

**Alkaloids of the Loganiaceæ.—Strychnin—Strychnina** (U. S.)— $\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_2$ —334—exists in the seeds and bark of different varieties of *strychnos*.

It crystallizes on slow evaporation of its solutions in orthorhombic prisms, by rapid evaporation as a crystalline powder;

very sparingly soluble in  $H_2O$  and in strong alcohol: soluble in 5 pts. chloroform. Its aqueous solution is intensely bitter, the taste being perceptible in a solution containing 1 pt. in 600,000.

It is a powerful base: neutralizes and dissolves in concentrated  $H_2SO_4$  without coloration; and precipitates many metallic oxides from solutions of their salts. Its salts are mostly crystallizable, soluble in  $H_2O$  and alcohol, and intensely bitter. The *acetate* is the most soluble. The *neutral sulphate* crystallizes, with 7 Aq., in rectangular prisms. The iodids of methyl and ethyl react with strychnin to produce the iodids of methyl or ethylstrychnium, white, crystalline, basic substances, producing an action on the economy similar to that of curare. When acted on by  $H_2SO_4$  and potassium chlorate, with proper precautions, *strychnic* or *igasuric acid* is formed.

ANALYTICAL CHARACTERS.—(1.) Dissolves in concentrated  $H_2SO_4$  without color. The solution deposits strychnin when diluted with  $H_2O$ , or when neutralized with magnesia or an alkali. (2.) If a fragment of potassium dichromate (or other substance capable of yielding nascent O) is drawn through a solution of strychnin in  $H_2SO_4$ , it is followed by a streak of color: at first blue (very transitory and frequently not observed), then a brilliant violet, which slowly passes to rose-pink, and finally to yellow. Reacts with  $\frac{1}{50000}$  grain of strychnin. (3.) A dilute solution of potassium dichromate forms a yellow, crystalline ppt. in strychnin solutions; which, when washed and treated with concentrated  $H_2SO_4$ , gives the play of colors indicated in 2. (4.) If a solution of strychnin be evaporated on a bit of platinum foil, the residue moistened with concentrated  $H_2SO_4$ , the foil connected with the + pole of a single Grove cell, and a platinum wire from the - pole brought in contact with the surface of the acid, a violet color appears upon the surface of the foil. (5.) Strychnin and its salts are intensely bitter. (6.) A solution of strychnin introduced under the skin of the back of a frog causes difficulty of respiration and tetanic spasms, which are aggravated by the slightest irritation, and twitching of the muscles during the intervals between the convulsions. With a small frog, whose surface has been dried before injection of the solution,  $\frac{1}{10000}$  grain of acetate of strychnin will produce tetanic spasms in 10 minutes. (7.) Solid strychnin, moistened with a solution of iodic acid in  $H_2SO_4$ , produces a yellow color, changing to brick-red and then to violet-red. (8.) Moderately concentrated  $HNO_3$  colors strychnin yellow in the cold. A pink or red color indicates the presence of brucin.

TOXICOLOGY.—Strychnin is one of the most active and most frequently used of poisons. It produces a sense of suffocation, thirst, *tetanic spasms*, usually opisthotonos, sometimes empros-

thotonos, occasionally vomiting, contraction of the pupils during the spasms, and death, either by asphyxia during a paroxysm, or by exhaustion during a remission. The symptoms appear in from a few minutes to an hour after taking the poison, usually in about 20 minutes; and death in from 5 minutes to 6 hours, usually within 2 hours. Death has been caused by  $\frac{1}{4}$  grain, and recovery has followed the taking of 20 grains.

The treatment should consist of the removal of the unabsorbed poison by the stomach-pump, injecting charcoal, and pumping it out after about 5 minutes; under the influence of chloroform if necessary. Chloral hydrate should be given.

Strychnin is one of the most stable of the alkaloids, and may remain for a long time in contact with putrefying organic matter without suffering decomposition.

**Brucin**— $C_{23}H_{26}N_2O_4 + 4Aq$ —394+72—accompanies strychnin. It forms oblique rhomboidal prisms, which lose their  $Aq$  in dry air. Sparingly soluble in  $H_2O$ ; readily soluble in alcohol, chloroform, and amyl alcohol; intensely bitter. It is a powerful base and most of its salts are soluble and crystalline. Its action on the economy is similar to that of strychnin, but much less energetic.

**ANALYTICAL CHARACTERS.**—(1.) Concentrated  $HNO_3$  colors it bright red, soon passing to yellow; stannous chlorid, or colorless  $NH_4HS$ , changes the red color to violet. (2.) Chlorin-water, or  $Cl$ , colors brucin bright red, changed to yellowish-brown by  $NH_4HO$ .

**Alkaloids of the Solanaceæ.**—**Solanin**— $C_{45}H_{71}NO_{16}$ —857—obtained from many species of *Solanum*; crystallizes in small, white, bitter, sparingly soluble prisms. Concentrated  $H_2SO_4$  colors it orange-red, passing to violet and then to brown. It is colored yellow by concentrated  $HCl$ . It dissolves in concentrated  $HNO_3$ , the solution being at first colorless, but after a time becomes purple.

**Atropin**—**Daturin**—**Atropina**, **U. S.**—**Atropia**, **Br.**— $C_{17}H_{23}NO_3$ —289—occurs in *Atropa belladonna* and in *Datura stramonium*. It forms colorless, silky needles, which are sparingly soluble in cold water, more readily soluble in hot water, very soluble in chloroform. It is odorless, but has a disagreeable, persistent, bitter taste. It is distinctly alkaline, and neutralizes acids with formation of salts. One of these, the sulphate—**Atropinæ sulphas**, **U. S.**—is a white, crystalline powder, readily soluble in water, which is the form in which atropin is usually administered.

**TOXICOLOGY.**—It is actively poisonous, producing drowsiness, dryness of the mouth and throat, dilatation of the pupils, loss of speech, diplopia, dizziness, delirium, coma.

The treatment should consist in the administration of emetics and the use of the stomach-pump.

**ANALYTICAL CHARACTERS.**—(1.) If a fragment of potassium dichromate be dissolved in a few drops of  $\text{H}_2\text{SO}_4$ , the mixture warmed, a fragment of atropin and a drop or two of  $\text{H}_2\text{O}$  added, and the mixture stirred, an odor of orange-blossoms is developed. (2.) A solution of atropin dropped upon the eye of a cat produces dilatation of the pupil. (3.) The dry alkaloid (or salt) is moistened with fuming  $\text{HNO}_3$  and the mixture dried on the water-bath. When cold it is moistened with an alcoholic solution of  $\text{KHO}$ —a violet color which changes to red.

When atropin is heated with concentrated  $\text{HCl}$  to  $120^\circ\text{--}130^\circ$  ( $248^\circ\text{--}266^\circ\text{ F.}$ ) for several hours, or when it is warmed with baryta-water to  $58^\circ$  ( $136.4^\circ\text{ F.}$ ) it is decomposed into a base related to the pyridins: **Tropin**— $\text{C}_7\text{H}_{11}\text{—OH, NCH}_3$ —and, at first, **tropic acid**— $\text{C}_8\text{H}_9\text{O}_3$ —but, later, **atropic acid**— $\text{CH}_2\text{—C(C}_6\text{H}_5\text{)COOH}$ . Tropin is also produced by a similar decomposition of hyoscyamin.

**Hyoscyamin**— $\text{C}_{15}\text{H}_{23}\text{NO}_3$ —occurs, along with another base, **hyoscin**, isomeric with atropin, in *Hyoscyamus niger*. It crystallizes, when pure, in odorless, white, silky needles whose taste is very sharp and disagreeable, and which are very sparingly soluble in water. As most commonly met with, it forms a yellowish, soft, hygroscopic mass which gives off a peculiar, tobacco-like odor. It neutralizes acids. Its sulphate—**Hyoscyaminæ sulphas**, **U. S.**—forms yellowish crystals, very soluble in water, hygroscopic, and neutral in reaction.

**Alkaloids from other Sources.**—**Ergotin**— $\text{C}_{50}\text{H}_{52}\text{N}_2\text{O}_8$ —and **Ecbolin** are two brown, amorphous, faintly bitter, and alkaline alkaloids obtained from ergot. They are readily soluble in water and form amorphous salts. The medicinal preparations known as ergotin are not the pure alkaloid.

**Colchicin**— $\text{C}_{17}\text{H}_{19}\text{NO}_5$ —occurs in all portions of *Colchicum autumnale* and other members of the same genus. It is a yellowish-white, gummy, amorphous substance, having a faintly aromatic odor and a persistently bitter taste. It is slowly but completely soluble in water, forming faintly acid solutions. It forms salts which are, however, very unstable.

Concentrated  $\text{HNO}_3$ , or, preferably, a mixture of  $\text{H}_2\text{SO}_4$ , and  $\text{NaNO}_3$  colors colchicin blue-violet. If the solution be then diluted with  $\text{H}_2\text{O}$ , it becomes yellow, and on addition of  $\text{NaHO}$  solution, brick-red.

**Veratrin**—**Veratrina**, **U. S.**— $\text{C}_{32}\text{H}_{52}\text{N}_2\text{O}_8$ —occurs in *Veratrum officinalis* = *Asagrua officinalis*, accompanied by **Sabadillin**— $\text{C}_{20}\text{H}_{26}\text{N}_2\text{O}_7$ —**Jervin**— $\text{C}_{30}\text{H}_{46}\text{N}_2\text{O}_8$ —and other alkaloids. The substance to which the name **Veratrina**, **U. S.**, applies is not the pure alkaloid, but a mixture of those occurring in the plant.

Concentrated  $\text{H}_2\text{SO}_4$  dissolves veratrin, forming a yellow solu-

tion turning orange in a few moments, and then, in about half an hour, bright carmine-red. Concentrated HCl forms a colorless solution with veratrin, which turns dark red when cautiously heated.

**Piperin**— $C_{17}H_{19}NO_3$ —occurs in black and white pepper. It crystallizes in colorless, transparent prisms; almost tasteless when pure; very sparingly soluble in water. It is a very weak base.

If piperin be heated with alcoholic KHO, it is decomposed into *piperidin*— $C_5H_{11}N$ —and *piperic acid*— $C_{12}H_{15}O_4$ . If piperidin be treated with silver oxid, pyridin (see p. 416) is formed.

**Berberin**—*Xanthopicroite*— $C_{20}H_{17}NO_4$ —occurs in *Berberis vulgaris*, *Cocculus palmatus*, and many other plants. It crystallizes in fine yellow needles or prisms; bitter in taste and neutral in reaction. It is difficultly soluble in cold water, readily soluble in alcohol and in boiling water. It forms well-defined, crystalline, yellow salts.

**Aconitin**— $C_{26}H_{35}NO_7(OH)_3O(CO, C_6H_5)$ —is an alkaloid obtained from *Aconitum napellus* and other species of *aconitum*. It is a colorless and odorless powder, possessed of an intensely bitter taste, and sharp, burning after-taste. It is strongly alkaline; almost insoluble in water, readily soluble in alcohol, ether, chloroform, or benzene. It neutralizes acids completely, with formation of well-defined, crystalline salts.

Aconite contains, besides aconitin, three other alkaloids, if not a greater number: **Napellin**, **acolyctin**, and **lycoctonin**. These three alkaloids, notably the first named, along with small quantities of aconitin, constitute the English or Morson's "aconitin," which is probably made from *Aconitum ferox*. Probably, also, all commercial samples of aconitin are mixtures of aconitin and napellin with lesser quantities of the other alkaloids and **aconin** and **pseudaconin**.

If aconitin be heated in sealed tubes with  $H_2O$  to 140–150 (284–302° F.) for several hours, it is decomposed into benzoic acid and **aconin**,  $C_{26}H_{35}NO_7(OH)_4$ .

A Japanese variety of aconite contains a peculiar alkaloid: **Japaconitin**,  $C_{56}H_{88}N_2O_2$ .

**ANALYTICAL CHARACTERS.**—(1.) Concentrated  $H_2SO_4$  dissolves aconitin, forming a light, yellow-brown solution, which slowly turns darker, and changes to light yellow on addition of  $HNO_3$ . (2.) If aconitin be dissolved in aqueous phosphoric acid, and the solution very gradually evaporated, a violet color is produced.

**TOXICOLOGY.**—Aconite and aconitin have been the agents used in quite a number of homicidal poisonings.

The symptoms usually manifest themselves within a few minutes; sometimes are delayed for an hour. There is numbness and tingling, first of the mouth and fauces, later becoming general. There is a sense of dryness and of constriction in the throat. Per-

sistent vomiting usually occurs, but is absent in some cases. There is diminished sensibility, with numbness, great muscular feebleness, giddiness, loss of speech, irregularity and failure of the heart's action. Death may result from shock if a large dose of the alkaloid be taken, but more usually it is by syncope.

The treatment should be directed to the removal of unabsorbed poison by the stomach-pump, and washing out of the stomach with infusion of tea holding powdered charcoal in suspension. Stimulants should be freely administered.

**Pilocarpin**— $C_{11}H_{16}N_2O_2$ —is the principal alkaloid of *jaborandi*. It forms a colorless, amorphous mass, readily soluble in water, alcohol, ether, and chloroform. It readily forms salts. Its chlorid—**Pilocarpinæ hydrochloras**, **U. S.**—occurs in white, deliquescent, odorless crystals.

**Cocain**— $C_{17}H_{21}O_4$ —is an alkaloid obtained from the leaves of *Erythroxylon coca*. It crystallizes in large, six-sided prisms. Its taste is at first bitter, producing paralysis of the sense of taste subsequently. It is strongly alkaline. Its chlorid, extensively used for the production of local anæsthesia, crystallizes in well-formed prismatic needles, readily soluble in water.

When heated with concentrated HCl, it is decomposed into benzoic acid, methyl alcohol, and a new base, **ecgonin**,  $C_8H_{15}NO_3$ .

**Physostigmin**—**Eserin**— $C_{16}H_{21}N_3O_2$ —is an alkaloid existing in the Calabar bean, *Physostigma venenosum*. It is a colorless, amorphous solid, odorless and tasteless, alkaline and difficultly soluble in water. It neutralizes acids completely, with formation of tasteless salts. Its salicylate—**Physostigminæ salicylas**, **U. S.**—forms short, colorless, prismatic crystals, sparingly soluble in water.

Concentrated  $H_2SO_4$  forms a yellow solution with physostigmin or its salts, which soon turns olive-green. Concentrated  $HNO_3$  forms with it a yellow solution. If a solution of the alkaloid in  $H_2SO_4$  be neutralized with  $NH_4HO$ , and the mixture warmed, it is gradually colored red, reddish-yellow, green, and blue.

**Curarin**— $C_{36}H_{35}N$  (?)—is an alkaloid obtainable from the South American arrow-poison, *curare*, or *woorara*. It crystallizes in four-sided, colorless prisms, which are hygroscopic, faintly alkaline, and intensely bitter.

Curarin dissolves in  $H_2SO_4$ , forming a pale violet solution, which slowly changes to red. If a crystal of potassium dichromate be drawn through the  $H_2SO_4$  solution, it is followed by a violet coloration, which differs from the similar color obtained with strychnin under similar circumstances, in being more permanent, and in the absence of the following pink and yellow tints.

**Emetin**— $C_{28}H_{40}N_2O_5$ —an alkaloid existing in *iperacuanha* which crystallizes in colorless needles or tabular crystals, slightly bitter and acid; odorless, and sparingly soluble in water.

It dissolves in concentrated  $\text{H}_2\text{SO}_4$ , forming a green solution, which gradually changes to yellow. With Fröhde's reagent it gives a red color, which soon changes to yellowish-green and then to green.

**Ptomains.**—This name, derived from  $\pi\tau\acute{o}\mu\alpha$ =that which is fallen—*i.e.*, a corpse—was first suggested by Selmi to apply to a class of substances, first distinctly recognized by him, which are produced from albuminoid substances under the influence of putrefactive decomposition, and which are distinctly alkaloidal in character.

The ptomains are possessed of all of the distinguishing characters of the vegetable alkaloids. They are alkaline in reaction, and combine with acids to form salts. Some are liquid, others are solid and crystalline. Some are actively poisonous, others are practically inert. They behave toward the general reagents for alkaloids in much the same way as do the vegetable alkaloids.

Although the names *ptomains* and *cadaveric alkaloids* are applied to alkaloids of animal origin, it is certain that such alkaloids may be and are produced during life in the animal economy.

It was feared that, as alkaloidal substances in many respects resembling those of vegetable origin are produced in the animal body, not only after death, but during life, grave doubts would be cast upon the results of analyses made to detect the presence of poisonous vegetable alkaloids in the cadaver in cases of suspected poisoning. Such fears were by no means groundless, as there is abundant evidence that ptomains have been mistaken for vegetable alkaloids in chemico-legal analyses. The ptomains, however, as well as the vegetable alkaloids, may be positively identified by a careful analysis, based upon the use, not of a single reaction, but of *all known reactions* for the alkaloid in question. Therefore, it is possible to positively predicate the existence or non-existence of a given vegetable alkaloid in a cadaver, but it can only be done after a thorough and conscientious examination by all physiological and chemical reactions.

The ptomains have of recent years assumed great importance to the physician by reason of their bearing upon the etiology of disease, and sufficient experimental evidence has already been obtained to warrant the belief that the method of action of many of the known pathogenic bacteria is by their production of alkaloidal poisons (see below).

One of the first of the putrid alkaloids to be formed in cadaveric matter is *cholin* (see pp. 276, 361), which undoubtedly has its origin in the decomposition of the lecithins.

**Neuridin**— $\text{C}_5\text{H}_{11}\text{N}_2$  (?)—is a diamine, related to *neurin* (see p. 277), which is formed during the early stages of cadaveric putrefaction. It is gelatinous, readily soluble in water, insoluble in

alcohol and ether, and very prone to decomposition, yielding dimethylamin and trimethylamin. It forms a chlorid which crystallizes in long, transparent needles, very soluble in water. It is non-poisonous.

**Cadaverin**— $C_5H_{14}N_2$ —identical with pentamethylenediamin,  $NH_2-(CH_2)_5-NH_2$ , is formed at a somewhat later stage of cadaveric putrefaction, along with putrescin and saprin (see below).

Its chlorid is crystalline, hygroscopic, very soluble in water, insoluble in strong alcohol and ether. Like most of the ptomains and several of the vegetable alkaloids, it gives a distinct blue color with ferric chlorid and potassium ferricyanid. It is non-poisonous.

**Putrescin**— $C_4H_{12}N_2$ —and **Caprin**— $C_5H_{16}N_2$ —are two non-poisonous diamins produced along with cadaverin. They are both liquid, and each forms a crystalline chlorid.

**Mydalein** is a putrid alkaloid, of undetermined composition, forming a difficultly crystallizable, hygroscopic chlorid, which is actively poisonous. Five milligrammes administered hypodermically to a cat causes death after profuse diarrhœa and secretion of saliva, violent convulsions, and paralysis, beginning with the extremities and extending to the muscles of respiration.

**Neurin** (see p. 277) is produced during the later stages of putrefaction. It is actively poisonous, and produces symptoms similar to those caused by muscarin. Atropin is a powerful antidote to its action.

**Mydin**— $C_5H_{11}NO$ —is a base produced after continued putrefaction at comparatively low temperatures. It is a powerful base and a strong reducing agent, and has an ammoniacal odor. It is non-poisonous.

**Mydatoxin**— $C_6H_{12}NO_2$ —is a strongly alkaline syrup, which produces, when administered to animals, violent clonic spasms, followed by paralysis and death.

Other ptomains produced during putrefaction of meat, fish, etc., are methylguanidin,  $C_2H_7N_3$ —poisonous; **muscarin**,  $C_5H_{15}NO_3$ —poisonous; and **gadinin**,  $C_7H_{17}NO_2$ —non-poisonous.

An alkaloid, many of whose chemical reactions have been determined, although its composition is unknown, has been obtained from the internal organs, and dejecta of cholera victims, as well as from cultures of the comma bacillus. This alkaloid, when administered to animals, causes symptoms of poisoning and death.

From the cultures of the Koch-Eberth typhus bacillus an alkaloid has been isolated—**Typhotoxin**,  $C_7H_{17}NO_2$ —which, when administered to animals, causes paralysis, copious diarrhœa, and death.

**Tetanin**— $C_{13}H_{30}N_2O_4$ —is an alkaloid obtained from cultures of a bacillus originating from a wound which had been the cause of death by tetanus. It forms a deliquescent chlorid, and a very

soluble chloroplatinate. The free base or its chlorid, when injected into mice or guinea-pigs, causes clonic or tonic convulsions of the greatest intensity, which terminate in death.

**Mytilotoxin**— $C_6H_{15}NO_2$ —is an alkaloid obtained from poisonous mussels, which, when administered to animals in small amount, causes the same symptoms as are produced by the mussels.

## ALBUMINOIDS AND GELATINOIDS.

### PROTEIN BODIES.

The substances of this class are never absent in living vegetable or animal cells, to whose "life" they are indispensable. They are as yet the products exclusively of the organized world.

**Physical Characters.**—They are almost all uncrystallizable and incapable of dialysis. Some are soluble in water, others only in water containing traces of other substances, others are insoluble. Their solutions are all levogyrous. Some are separated as solids from their solutions, in a permanently modified form, by heat and by certain reagents; a change called **coagulation**. When once coagulated they cannot be redissolved. The temperature at which coagulation by heat occurs varies with different albuminoids, and is of value in distinguishing them from one another.

**Composition.**—They consist of C, N, H, O, and usually a small quantity of S, and form highly complex molecules, whose exact composition is uncertain. Of their *constitution* nothing is definitely known, although there is probability that they are highly complex anids, related to the ureids, and formed by the combination of glycollamin, leucin, tyrosin, etc., with radicals of the acetic and benzoic series.

**General Reactions.**—They all respond to the following tests:

(1.) A purple-red color when warmed to 70° (158° F.) with Milon's reagent. The reagent is made by dissolving, by the aid of heat, 1 pt. Hg in 2 pts.  $\text{HNO}_3$  of sp. gr. 1.42, diluting with 2 vols.  $\text{H}_2\text{O}$ , and decanting after 24 hours. (2.) A yellow color with  $\text{HNO}_3$ ; changing to orange with  $\text{NH}_4\text{HO}$  (xanthoproteic reaction). (3.) A purple color with Pettenkofer's test (*q.r.*). (4.) With a drop or two of cupric sulphate solution and liquor potassæ a violet color. (5.) A solution of an albuminoid in excess of glacial acetic acid is colored violet and rendered faintly fluorescent by concentrated  $\text{H}_2\text{SO}_4$ . (6.) With potassium ferrocyanid, in solutions strongly acid with acetic acid, a white ppt.

**Decompositions.**—Dilute acids decompose them into two substances: one insoluble, amorphous, yellowish, called **hemiprotein**; the other soluble in water, insoluble in alcohol, faintly acid, called **hemialbumin**. A prolonged boiling with moderately concentrated  $\text{H}_2\text{SO}_4$  decomposes them, forming well-defined substances—glycecol, leucin, tyrosin; aspartic and glutamic acids. Alkalies dissolve them more or less readily: on boiling the solution, part of the sulphur is converted into sulphid and hyposulphite. Their alkaline solutions, when neutralized by acids, de-

posit Mulder's protein. Concentrated alkalies decompose them into amido-acids: By fusion with alkalies, alkaline cyanids are also produced. When they are heated with caustic baryta and water at 100 (212 F.), carbonate, sulphate, oxalate, and phosphate of barium are deposited, and  $\text{CO}_2$  and  $\text{NH}_3$  are given off in the same proportions as when urea is similarly treated; when the temperature is raised, under pressure, finally to 200 (392 F.), a crystalline mass is formed which contains oxalic and acetic acids, a number of amido-acids, aspartic and glutamic acids, and a substance resembling dextrin. Heated with  $\text{H}_2\text{O}$ , under pressure, they are partly dissolved and partly decomposed. A mixture of  $\text{H}_2\text{SO}_4$  and manganese dioxid, or potassium dichromate, produces aldehydes, and acids of the fatty and benzoic series, hydrocyanic acid, and cyanids from the albuminoids. When heated under pressure with Br and  $\text{H}_2\text{O}$  they yield  $\text{CO}_2$ , oxalic and aspartic acids, amido-acids, and bromin derivatives of the fatty and benzoic series. Potassium permanganate produces from them urea,  $\text{CO}_2$ ,  $\text{NH}_3$  and  $\text{H}_2\text{O}$ .

Putrefaction is a decomposition of dead albuminoid and gelatinous matter, attended by the evolution of fetid gas, and by the appearance of low forms of organized beings (bacteria).

That it may occur there must have been contact with air, and there must be presence of moisture, and a temperature between 5-90° (41-194 F.). It is attended by the breaking down and liquefaction of the material if it be solid; or its clouding and the formation of a scum upon the surface if it be liquid. The products of putrefaction vary with the conditions under which it occurs. The most prominent are: N, H, hydrocarbons,  $\text{H}_2\text{S}$ ,  $\text{NH}_3$ ,  $\text{CO}_2$ , certain ill-defined phosphorized and sulphurated bodies, acids of the acetic and lactic series, amido-acids, and alkaloidal substances.

Under certain imperfectly defined conditions, buried animal matter is converted into a substance resembling tallow, and called adipocere, which consists chiefly of palmitate, stearate, and oleate of ammonium, phosphate and carbonate of calcium, and an undetermined nitrogenous substance.

Putrefaction may be prevented by: (1) exclusion of air; (2) removal of water; (3) maintaining the temperature below 5° (41 F.); (4) the action of antiseptics.

Antiseptics are substances which prevent or restrain putrefaction.

Deodorizers, or air purifiers, are substances which destroy the odorous products of putrefaction.

Disinfectants are substances which restrain infectious diseases by destroying their specific poisons.

Certain substances are antiseptic, deodorant, and disinfectant;

such are: chlorin, bromin, iodin, the hypochlorites, and sulphur dioxid; others lack one of the powers, as the mineral acids and the non-volatile "disinfectants," which are antiseptic and disinfectant, but not deodorant. Still others exert but one of the powers, as water and air, which may be mechanical deodorants, but neither disinfectants nor antiseptics.

There occurs a decomposition of vegetable tissues under the influence of warmth and moisture, which is known as *eremacausis*, differing from putrefaction in that the substances decomposed are the carbohydrate instead of the azotized constituents, and in the products of the decomposition, there being no fetid gases evolved (except there be simultaneous putrefaction), and the final product is a brownish material (humus or ulmin).

**Classification.**—In the present unsatisfactory state of our knowledge of the chemical constitution of these substances, we can only adopt a temporary classification, based upon their physical and physiological characters.

#### A. ALBUMINOIDS:

I. *Soluble in pure water; coagulated by heat.*—The true *albumins* of the white of egg, serum, and vegetable albumin.

II. *Insoluble in pure water; soluble in water without alteration in presence of neutral salts, alkalies and acids; and capable of precipitation unchanged from these solutions.*

1. *Globulins.*—Vitellin, myosin, paraglobulin, fibrinogen.

2. *Animal caseins.*—Milk casein, serum casein.

3. *Vegetable caseins.*—Gluten casein, legumin, conglutin.

4. *First terms of decomposition of the albuminoids by acids, alkalies and cryptolytes.*—Albuminates (so called), acid albumin, syntonin, hemiprotein, peptone.

III. *Insoluble in water and only soluble after decomposition. Cannot be separated without alteration from their solutions in acids and alkalies.*—Gluten fibrin, gliadin, mucedin.

IV. *Coagulated.*—Coagulated albumin and fibrin.

V. *Amyloid matter.*—Lardacein.

#### B. GELATINOIDS:

I. *Collagenes.*—Collagen, elastin, ossein and its derivatives, chondrigen (?), chondrin (?), gelatin, keratin.

II. *Mucilaginous bodies.*—Mucin, paralbumin, colloidin.

### ALBUMINOIDS.

I.—**Egg albumin** exists in solution, imprisoned in a network of delicate membranes, in the white of egg. It is obtained in an impure condition by cutting the whites of eggs with scissors, expressing through linen, diluting with an equal volume of water, filtering, and concentrating the filtrate at a temperature below

40° (104° F.); mineral salts, which adhere to it tenaciously, are separated by dialysis. It is a mixture of two kinds of proteids. (1.) Those coagulable by heat. Of these, two are globulins (*q.v.*) precipitable by  $MgSO_4$ . Their coagulation temperatures are: oviglobulin  $\alpha$ , 57.5° (135.5° F.); oviglobulin  $\beta$ , 67° (152.6° F.). Three are albumins which coagulate:  $\alpha$  at 72° (161.6° F.),  $\beta$  at 76° (168.8° F.), and  $\gamma$  at 82° (179.6° F.). (2.) Peptones, which increase in amount with the staleness of the egg.

Solutions of egg albumin are not precipitated by a small quantity of HCl, but an excess of that acid produces a deposit which is difficultly soluble in HCl,  $H_2O$ , and salt solution. Its characteristic reaction is that it is coagulated by agitation with ether.

Serum-albumin exists in blood-serum, chyle, lymph, pericardial fluid, the fluids of cysts and of transudations, in milk and, pathologically, in the urine. It is best obtained from blood-serum, after removal of paraglobulin (*q.v.*), by a tedious process, and only then in a state of doubtful purity. It is less abundant in the blood of some animals than paraglobulin, but more abundant in that of man.

Solutions of serum-albumin are levogyrous  $[\alpha]_D = -56^\circ$ ; they are not precipitated by  $CO_2$ , by acetic or phosphoric acid, by ether or by magnesium sulphate. They are precipitated by mineral acids, tannic acid, metaphosphoric acid, and most metallic salts. When heated they become opalescent at 60° (140° F.), and coagulate in the flocculent form at 72–75° (161.6–167° F.).

Human serum-albumin consists of three distinct proteids  $\alpha$ ,  $\beta$ , and  $\gamma$ , coagulating at 73° (163.4° F.), 77° (170.6° F.), and 84° (183.2° F.). The blood of some animals contains but two of these. They are all precipitated, after removal of serum-globulin by saturation with  $MgSO_4$ , by saturation with  $Na_2SO_4$ . Potassium acetate also precipitates them without coagulation.

**Detection and Determination of Albumin in Urine.**—If the urine be not perfectly clear it is filtered; if this do not render it *perfectly* transparent, it is treated with a few drops of magnesia mixture (p. 120, note), and again filtered. The filtrate, if alkaline, is rendered *just* acid by adding dilute acetic acid guttatim (nitric acid should not be used, and the acidulation of alkaline urine is imperative). The urine is now heated to near boiling, and if a cloudiness or precipitate be formed,  $HNO_3$  is added slowly to the extent of about 10 drops. If heat produce a cloudiness, which clears up completely on addition of  $HNO_3$ , it is due to an excess of earthy phosphates. If a cloudiness produced by heat do not clear up (it may increase) on addition of  $HNO_3$ , it is due to albumin.

Small quantities of albumin may sometimes be better detected

by **Heller's test**: A layer of  $\text{HNO}_3$  is placed in a test-tube, which is then held at an angle, and the urine allowed to flow *slowly* upon the surface of the  $\text{HNO}_3$  (Fig. 42) so as to form a distinct layer, with the

FIG. 42.

minimum of mixing of the two liquids. The test-tube is then brought to the vertical slowly, and the point of junction of the two liquids examined against a dark background. If albumin be present a white, opaque band, whose upper and lower borders are *sharply defined*, will be seen at the line of junction of the two liquids. When urates are present in excess, a white band will be observed, but its position will be rather above the line of junction, and its upper border will not be sharply defined,

but gradually diminished in density from below upward. In non-albuminous urines there is usually a darkening, but never an opacity at the line of junction.

**QUANTITY.**—The only method of determining the quantity of albumin in urine, with an approach to accuracy, is gravimetric: 20–50 c.c. (5.4–13.5 fl. ȳ) of the filtered urine (according as the qualitative testing shows albumin to be present in large or small quantity) are diluted with an equal volume of water, and slowly heated over the water-bath. As the boiling temperature is approached, 3–4 drops of dilute acetic acid are added. After the urine has boiled for a few moments, and the coagulated albumin has become flocculent, it is thrown upon a dried and weighed filter. The coagulum is washed with boiling  $\text{H}_2\text{O}$ , then with  $\text{H}_2\text{O}$  acidulated with  $\text{HNO}_3$ , then with alcohol, and finally with ether. By these washings impurities are removed, and the albumin is caused to contract firmly. The filter and the albumin are dried at  $110^\circ$  ( $230^\circ \text{F.}$ ) until they cease to lose weight, and again weighed. The difference between the two weighings is the weight of dry albumin in the volume of urine used.

**Vegetable albumin**—exists in solution in all vegetable juices, and forms the most valuable constituent of those vegetables which are used as food. It is coagulated from its solutions at  $61^\circ$ – $63^\circ$  ( $141.8^\circ$ – $145.4^\circ \text{F.}$ ), and by nearly all acids.

**II.—Vitelin** exists in the yolk of egg and in the crystalline lens. It is soluble in dilute solution of sodium chlorid, from which it is precipitated by excess of  $\text{H}_2\text{O}$ ; by heating to  $75^\circ$ – $80^\circ$  ( $167^\circ$ – $176^\circ \text{F.}$ ); and by alcohol. It is not precipitated by solid sodium chlorid. It dissolves in weak alkaline solutions without alteration, and in

very dilute HCl (1-1000), by which it is quickly converted into syntonin.

**Myosin**—is one of the principal constituents of the muscular fibre in rigor mortis. It is a faintly yellow, opalescent, distinctly alkaline liquid, which, when dropped into distilled H<sub>2</sub>O, deposits the myosin in globular masses, while the H<sub>2</sub>O assumes an acid reaction. It is insoluble in H<sub>2</sub>O, easily soluble in dilute salt solution, from which it is precipitated by the addition of solid sodium chlorid, or by a heat of 55-60° (131-140° F.). Very dilute HCl dissolves and converts it into syntonin.

**Paraglobulin**.—This substance has been described by various authors under the names: *plasmin* (Denis), *serum casein* (Panum), *serum globulin*, *fibrino-plastic matter* (Schmidt), *serin* (Denis). It exists in blood-serum, in pericardial fluid, hydrocele fluid, lymph and chyle, and, accompanying serum-albumin, in albuminous urine. It is obtained by diluting blood-serum, or hydrocele fluid, with 10-15 volumes of ice-cold H<sub>2</sub>O, treatment of the solution with strong current of CO<sub>2</sub>, and washing the collected deposit with H<sub>2</sub>O as long as a portion of the filtrate precipitates with acetic acid and potassium ferrocyanid, or with silver nitrate. It is a granular substance, which gradually becomes more compact; insoluble in H<sub>2</sub>O, sparingly soluble in H<sub>2</sub>O containing CO<sub>2</sub>; soluble in dilute alkalies, in lime-water, in solutions of neutral alkaline salts, in dilute acids. Its solution in very dilute alkaline fluids is perfectly neutral and is not coagulated by heat, except after *faint* acidulation with acetic or mineral acids; it is precipitated by a large volume of alcohol; its solutions are also precipitated incompletely by dissolving sodium chlorid in them to saturation, and completely by similar solution of magnesium sulphate; this last method of precipitation is used for the separation of paraglobulin from serum-albumin (see Fibrin).

**Fibrinogen**.—After the separation of paraglobulin from blood-plasma, as described above, if the liquid be still further diluted, and again treated with CO<sub>2</sub>, a substance is obtained which, although closely resembling paraglobulin in many characters, is distinct from it, and, unlike paraglobulin, it cannot be obtained from the serum separated from coagulated blood.

Paraglobulin and fibrinogen are both soluble in a solution of sodium chlorid containing 5-8 per cent. of the salt; when the degree of concentration of the salt solution is raised to 12-16 per cent., the fibrinogen is precipitated, while the paraglobulin remains in solution and is only precipitated, and then incompletely, when the percentage of salt surpasses twenty (see Fibrin).

**Milk casein**—the most abundant of the albuminoids of the milk of mammalia, closely resembles alkali albuminates, with which it is probably identical, as the main point of distinction

has been found to be without significance. Unlike pure alkali albuminates, casein is coagulated from its solution by rennet (the product of the fourth stomach of the calf) at 40° (104° F.); but it has been found that alkali albuminate is also so coagulated when milk-sugar and fat are added to the solution.

**Milk.**—The secretion of the mammary gland is water holding in solution casein, albumin, lactose, and salts; and fat and casein in suspension. **Cream** consists of the greater part of the fat, with a small proportion of the other constituents of the milk. **Skim-milk** is milk from which the cream has been removed. **Butter-milk** is cream from which the greater part of the fat has been removed, and consequently is of about the same composition as skim-milk.

The composition of milk differs in animals of different species :

	Human.	Cow.	Goat.	Sheep.	Ass.	Mare.	Cream	Condensed Milk.
Water....	88.35	84.28	86.85	83.30	89.01	90.45	45.99	25.68
Solids....	11.65	15.72	13.52	16.60	10.99	9.55	54.01	74.32
Casein....	3.15	3.57	2.53	5.73	3.57	2.53	6.33	16.83
Albumin..		0.78	1.26					
Fat .....	3.87	6.47	4.34	6.05	1.85	1.31	43.97	10.27
Lactose...	4.37	4.34	3.78	3.96	5.05	5.43	3.28	44.33*
Salts .....	0.26	0.63	0.65	0.68				

\* Including 28.98 parts of cane-sugar.

The composition of cows' milk varies considerably, according to the age, condition, breed, and food of the cow; to the time and frequency of milking; and to whether the sample examined is from the first, middle, or last part of each milking.

Cows' milk is very frequently adulterated, both by the removal of the cream and the addition of water. For ordinary purposes, the purity of the milk may be determined by observing the sp. gr. and the percentage of cream by the lactometer and creamometer, *neither of which, used alone, affords indications which can be relied upon.* The sp. gr. should be observed at the temperature for which the instrument is made, as in a complex fluid such as milk no valid correction for temperature is practical; it ranges in pure milk from 1027 to 1034, it being generally the lower in milk which has been watered, and in such as is very rich in cream, and the higher the less cream is present. The average sp. gr. is 1030; the average percentage of cream 13.

The percentage of cream is determined by the creamometer: a glass tube about a foot long and half an inch in diameter, the upper fifth (excluding about an inch from the top) being graduated into hundredths of the whole, the 0 being at the top. To

use it, it is simply filled to the 0 with the milk to be tested, set aside for twenty hours and the point of separation between milk and cream read off. It should be above eight per cent.

This method of determining the purity of milk, although sufficient for ordinary purposes, should not be considered as affording evidence upon which to base legal proceedings; in such cases nothing short of a chemical determination of the percentage of fats, and of solids not fat, should be accepted as evidence of the impurity of milk.

**Serum-casein**—is a substance obtained from blood-serum diluted with 10 volumes of  $H_2O$ , freed from paraglobulin by  $CO_2$ , and from albumin by acetic acid and heat. It is insoluble in salt solutions, slowly soluble in a one-per-cent. solution of sodium hydrate. Such a solution is partially precipitated by  $CO_2$ , almost completely by acetic acid, and completely by treating with excess of powdered sodium chlorid; incompletely soluble in dilute  $HCl$ .

**Gluten-casein**—that portion of crude gluten (a soft, elastic, grayish material best obtained from flour) which is insoluble in alcohol, hot or cold; **Legumin**—a sparingly soluble albuminoid obtained from peas, beans, etc.; and **Conglutin**—a substance closely related to legumin and to gliadin, but differing from them in some characters, obtained from almonds, are three vegetable albuminoids resembling casein.

They are insoluble in pure water, readily soluble in dilute alkaline solutions, from which they are precipitated by acids and by rennet.

**Alkali albuminates**—proteins of Hoppe-Seyler—are formed when an albuminoid is dissolved in concentrated solutions of potassium and sodium hydrates; it is very probable that they are identical with serum and milk-casein.

**Acid albumins**—are substances obtained by precipitating solutions of albuminoids by the simultaneous addition of an acid and a large quantity of a neutral salt; they vary exceedingly in composition and properties.

**Syntonin**—**Parapeptone**—**Albumose**—is extracted from contractile tissues. The same substance is formed by the action of dilute acids upon the albuminoids, and as the first product of the action of the gastric juice, or of mixtures of pepsin and dilute acid upon albuminoids. It resembles serum-casein closely, the only divergence in their properties being that syntonin is much more readily soluble in a 0.1-per-cent. solution of  $HCl$ , and in faintly alkaline liquids.

**Peptone**—**Albuminose**—is the product of the action of the gastric and pancreatic juices upon albuminoids during the process of digestion. It is soluble in  $H_2O$ , insoluble in alcohol and in ether. Its watery solution is neutral, not precipitable by acids or alkalis.

lies, or by heat when faintly acid. Alcohol precipitates it in white, casein-like flocks, which, if slowly heated to 90° (194° F.), while still moist form a transparent, yellowish liquid, and, on cooling, an opaque, yellowish, glassy mass. It has a greater power than other albuminoids of combining with acids and bases.

The most important character of peptone, in which it differs from other albuminoids, is that it is readily dialyzable. Its presence in the blood has not been demonstrated, and it is probable that immediately upon its entrance into the circulation it is converted into albuminoids resembling, yet differing from, those from which it was derived.

Peptone is produced by the action of many chemical reagents upon albuminoids; and also as one of the first products of putrefaction. When produced by putrefaction, or by artificial digestion, it is accompanied by **peptotoxin**, a crystallizable and actively poisonous alkaloidal substance.

It has been claimed that the gastric digestion of different albuminoids produces, not a single substance, but a distinct peptone for each albuminoid. If such be the case, and the present state of our knowledge does not permit of a definite answer to the question, these bodies are very closely related.

Peptone responds to the general reactions for the albuminoids (see p. 458), from which it may be distinguished by the *biuret reaction*. If a mere trace of  $\text{CuSO}_4$  solution be added to a solution of peptone and then  $\text{KHO}$  or  $\text{NaHO}$  solution, a purple or reddish-violet color is produced. A similar appearance is produced with acid albumins.

IV.—**Coagulated albumins**—are obtained, as described above, from the soluble varieties by the action of acids, heat, alcohol, etc. They are insoluble in water, alcohol, solutions of neutral salts; difficultly soluble in dilute alkaline solutions. In acetic acid they swell up and dissolve slowly; from this solution they are precipitated by concentrated salt solution. Concentrated  $\text{HCl}$  dissolves them with formation of syntonin. By the action of gastric juice, natural or artificial, they are converted first into syntonin, then into peptone.

**Fibrin**—is obtained when blood is allowed to coagulate or is whipped with a bundle of twigs. When pure it is at first a gelatinous mass, which contracts to a white, stringy, tenacious material, made up of numerous minute fibrils; when dried it is hard, brittle, and hygroscopic. It is insoluble in water, alcohol, ether; in dilute acid it swells up and dissolves slowly and incompletely. When heated with water to 72° (161°.6 F.), or by contact with alcohol, it is contracted, and is no longer soluble in dilute acids, but soluble in dilute alkalis. In solutions of many neutral salts of 6-10 per cent., it swells up and is partially dissolved; from this

solution it separates on the addition of water, or upon the application of heat to 73° (163° F.), or by acetic acid or alcohol. Moist fibrin has the property of decomposing hydrogen peroxid with copious evolution of oxygen.

Fibrin does not exist as such in the blood, and the method of its formation and of the clotting of blood has been the subject of much experiment and argument; nor can the question be said to be definitely set at rest. In the light of the researches of Denis, Schmidt, and especially of Hammarsten, it may be considered as almost proven that fibrin is formed from fibrinogen under favorable circumstances, and by a transformation which is not yet understood. Whether paraglobulin plays any part directly in the formation of fibrin or not, is still an open question.

V.—**Amyloid**—is a pathological product, occurring in fine grains, resembling starch-granules in appearance, in the membranes of the brain and cord, in waxy and lardaceous liver, and in the walls of the blood-vessels. Its composition is that of the albuminoids, from which it differs in being colored red by iodine; violet or blue by iodine and  $H_2SO_4$ . Soluble in  $HCl$  with formation of syntonin; and in alkalies. It is not attacked by the gastric juice, and is not as prone to putrefaction as the other albuminoids.

#### GELATINOIDS.

I.—**Collagen**.—Bony tissue is made up mainly of tricalcic phosphate, combined with an organic material called *osseine*, which is a mixture of collagen, elastin, and an albuminoid existing in the bone-cells. Collagen also exists in all substances which, when treated with  $H_2O$ , under the influence of heat and pressure, yield gelatin. It is insoluble in cold  $H_2O$ , but by prolonged boiling is converted into gelatin, which dissolves. It is dissolved by alkalies.

**Gelatin**—obtained as above, from ossein, exists in the commercial product of that name, and in a less pure form in glue. When pure it is an amorphous, translucent, yellowish, tasteless substance, which swells up in cold  $H_2O$ , without dissolving, and forms, with boiling  $H_2O$ , a thick, sticky solution, which on cooling becomes, according to its concentration, a hard glassy mass or a soft jelly—the latter even when the solution is very dilute. It is insoluble in alcohol and ether, but soluble, on warming, in glycerin; the solution in the last-named liquid forms, on cooling, a jelly which has recently been applied to various contrivances for copying writing. A film of gelatin impregnated with potassium dichromate becomes hard and insoluble on exposure to sunlight.

**Chondrin** is the name given to a substance obtained from car-

tilaginous tissue and supposed to be distinct from gelatin. It is probably a mixture of gelatin and mucin.

**Elastin**—is obtained from elastic tissues by successive treatment with boiling alcohol, ether, water, concentrated acetic acid, dilute potash solution, and water. It is fibrous, yellowish; swells up in water and becomes elastic; soluble with a brown color in concentrated potash solution. It contains no S, and on boiling with  $\text{H}_2\text{SO}_4$  yields glycol.

**Keratin**—is the organic basis of horny tissues, hair, nails, feathers, whalebone, epithelium, tortoise-shell, etc. It is probably not a distinct chemical compound, but a mixture of several closely related bodies.

Keratin, prepared by boiling quills in strong acetic acid for 24 hours, filtering and evaporating over the water-bath, is now used as a coating for pills intended to pass through the stomach without solution; the coating being insoluble in the acid gastric secretion, but soluble in the alkaline liquids of the intestine.

II.—**Mucin**—is a substance containing no S and existing in the different varieties of mucus, in certain pathological fluids, in the bodies of mollusks, in the saliva, bile, connective tissues, etc. Its solutions, like the fluids in which it occurs, are viscid. It is precipitated by acetic acid and by  $\text{HNO}_3$ , but is dissolved by an excess of the latter; it dissolves readily in alkaline solutions, and swells up in  $\text{H}_2\text{O}$ , with which it forms a false solution. It is not coagulated by heat.

## ANIMAL CRYPTOLYTES.

## SOLUBLE ANIMAL FERMENTS.

Under this head are classed substances somewhat resembling the albuminoids, of unknown composition, occurring in animal fluids, and having the power of effecting changes in other organic substances, the method of whose action is undetermined.

**Ptyalin**—is a substance occurring in saliva, and having the power of converting starch into dextrin and a sugar resembling glucose (ptyalose), in liquids having an alkaline, neutral, or faintly acid reaction.

**Pepsin**—is the cryptolyte of the gastric juice. Attempts to separate it without admixture of other substances have hitherto proved fruitless; nevertheless, mixtures containing it and exhibiting its characteristic properties more or less actively have been obtained by various methods. The most simple consists in macerating the finely divided mucous membrane of the stomach in alcohol for 48 hours, and afterward extracting it with glycerin; this forms a solution of pepsin, which is quite active, and resists putrefaction well, and from which a substance containing the pepsin is precipitated by a mixture of alcohol and ether.

If pepsin be required in the solid form, it is best obtained by Brücke's method. The mucous membrane of the stomach of the pig is cleaned and detached from the muscular coat by scraping; the pulp so obtained is digested with dilute phosphoric acid at 38° (100.4 F.), until the greater part of it is dissolved; the filtered solution is neutralized with lime-water; the precipitate is collected, washed with H<sub>2</sub>O, and dissolved in dilute HCl; to this solution a saturated solution of cholesterin, in a mixture of 4 pts. alcohol and 1 pt. ether, is gradually added; the deposit so formed is repeatedly shaken with the liquid, collected on a filter, washed with H<sub>2</sub>O and then with dilute acetic acid, until all HCl is removed; it is then treated with ether and H<sub>2</sub>O: the former dissolves cholesterin and is poured off, the latter the pepsin; after several shakings with ether the aqueous liquor is evaporated at 38° (100.4 F.), when it leaves the pepsin as an amorphous, grayish-white substance; almost insoluble in pure H<sub>2</sub>O, readily soluble in acidulated H<sub>2</sub>O; probably forming a compound with the acid, which possesses the property of converting albuminoids into peptone.

The so-called *Pepsina porci* is either the calcium precipitate obtained as described in the first part of the above method, or, more commonly, the mucous membrane of the stomach of the pig, scraped off, dried, and mixed with rice-starch or milk-sugar.

**Pancreatin.**—Under this name, substances obtained from the pancreatic secretion, and from extracts of the organ itself, have been described, and to some extent used therapeutically. They do not, however, contain all the cryptolytes of the pancreatic juice, and in many instances are inert albuminoids. The actions of the pancreatic juice are: (1) it rapidly converts starch, raw or hydrated, into sugar; (2) in alkaline solution—its natural reaction—it converts albuminoids into peptone; (3) it emulsifies neutral fats; (4) it decomposes fats, with absorption of  $H_2O$  and liberation of glycerin and fatty acids.

The pancreatic secretion probably contains a number of cryptolytes—certainly two. The one of these to which it owes its peptone-forming power has been obtained in a condition of comparative purity by Kühne, and called by him **trypsin**; in aqueous solution it digests fibrin almost immediately, but it exerts no action upon starch.

The diastatic (sugar-forming) cryptolyte of the pancreatic juice has not been separated, although a glycerin extract of the finely divided pancreatic tissue contains it, along with trypsin.

## ANIMAL COLORING MATTERS.

**Hæmoglobin and its Derivatives—*Hæmato-crystallin*.**—The coloring matter of the blood is a highly complex substance, resembling the albuminoids in many of its properties, but differing from them in being crystallizable and in containing iron.

Hæmoglobin exists in the red-blood corpuscles in two conditions of oxidation; in the form in which it exists in arterial blood it is loosely combined with a certain quantity of oxygen, and is known as *oxyhæmoglobin*. The mean of many nearly concurring analyses shows its composition to be  $C_{600}H_{950}N_{151}FeS_2O_{29}$ . When obtained from the blood of man and from that of many of the lower animals, it crystallizes in beautiful red prisms or rhombic plates; that from the blood of the squirrel in hexagonal plates; and that from the guinea-pig in tetrahedra. The crystals are always doubly refracting. It may be dried in vacuo at  $0^\circ$  ( $32^\circ$  F.); if thoroughly dried below  $0^\circ$  ( $32^\circ$  F.), it may be heated to  $100^\circ$  ( $212^\circ$  F.) without decomposition, but the presence of a trace of moisture causes its decomposition at a much lower temperature. Its solubility in water varies with the species of animal from whose blood it was obtained; thus, that from the guinea-pig is but sparingly soluble, while that from the pig is very soluble. It is also dissolved unchanged by very weak alkaline solutions, but is decomposed by acids or salts having an acid reaction.

**Hæmoglobin, or reduced hæmoglobin**, is formed from oxyhæmoglobin in the economy during the passage of arterial into venous blood; and by the action of reducing agents, or by boiling its solution at  $40^\circ$  ( $104^\circ$  F.) in the vacuum of the mercury pump.

Oxyhæmoglobin is of a much brighter color than the reduced, and has a different absorption spectrum. The spectrum of oxyhæmoglobin varies with the concentration. In concentrated solutions the light is entirely absorbed, in more dilute solutions the spectrum 10, Fig. 16, is observed, and in still further dilutions 11, Fig. 16; in which the band at D is narrower, darker, and more sharply defined than the other. In highly diluted solution the band at D is alone visible. The spectrum of hæmoglobin consists of a single band much broader and fainter than either of the oxyhæmoglobin bands (12, Fig. 16).

Hæmoglobin, in contact with O or air, is immediately converted into oxyhæmoglobin. With CO it forms a compound resembling oxyhæmoglobin in the color of its solution, but in which the CO cannot be replaced by O; for which reason hæmoglobin, once combined with CO, becomes permanently unfit to fulfil its function in respiration (see p. 323).

When a solution of oxyhæmoglobin is boiled, it becomes turbid, and a dirty, brownish-red coagulum is deposited; the hæmoglobin has been decomposed into an albuminoid (or mixture of albuminoids), called by Preyer **globin**, and **hæmatin**. The latter, at one time supposed to be the blood-coloring matter, is a blue-black substance, having a metallic lustre and incapable of crystallization. It is insoluble in water, alcohol, ether, and dilute acids; soluble in alkaline solutions. It has the composition  $C_{68}H_{70}N_8Fe_2O_{10}$ . Its alkaline solutions exhibit the spectrum 13, Fig. 16. Although itself uncrystallizable, hæmatin combines with HCl to form a compound which crystallizes in rhombic prisms, and which is identical with the earliest known crystalline blood-pigment, **hæmin**, or **Teichmann's crystals**.

When reduced hæmoglobin is decomposed as above, in the absence of oxygen, hæmatin is not produced, but a substance identical with that called **reduced hæmatin**, and called by Hoppe-Seyler **hæmocromogen**; whose spectrum is shown in 14, Fig. 16.

If a solution of hæmoglobin be exposed for some time to air it changes in color from red to brownish, and assumes an acid reaction; it then exhibits the spectrum 15, Fig. 16, due to the production of **methæmoglobin**, probably a stage in the conversion of hæmoglobin into hæmatin and globin.

**Biliary pigments.**—There are certainly four, and probably more, pigmentary bodies obtainable from the bile and from biliary calculi, some of which consist in great part of them.

**Bilirubin**— $C_{32}H_{36}N_4O_6$ —is, when amorphous, an orange-yellow powder, and when crystalline, in red rhombic prisms. It is sparingly soluble in  $H_2O$ , alcohol, and ether; readily soluble in hot chloroform, carbon disulphid, benzene, and in alkaline solutions. When treated with  $HNO_3$  containing nitrous acid, or with a mixture of concentrated  $HNO_3$  and  $H_2SO_4$ , it turns first green, then blue, then violet, then red, and finally yellow. This reaction, known as Gmelin's, is very delicate, and is used for the detection of bile-pigments in icteric urine and in other fluids.

**Biliverdin**— $C_{32}H_{36}N_4O_8$ —is a green powder, insoluble in  $H_2O$ , ether, and chloroform, soluble in alcohol and in alkaline solutions. It exists in green biles, but its presence in yellow biles or biliary calculi is doubtful. It responds to Gmelin's test. In alkaline solution it is changed after a time into biliprasin.

**Bilifuscin**— $C_{16}H_{20}N_2O_4$ —obtained in small quantity from human gall-stones, is an almost black substance, sparingly soluble in  $H_2O$ , ether, and chloroform; readily soluble in alcohol and in dilute alkaline solutions. Its existence in the bile is doubtful.

**Biliprasin**— $C_{16}H_{22}N_2O_6$  (?)—exists in human gall-stones, in ox-gall, and in icteric urine. It is a black, shining substance, insol-

uble in  $H_2O$ , ether, and chloroform; soluble in alcohol and in alkaline solutions.

**Urobilin—Hydrobilirubin— $C_{32}H_{40}N_4O_7$ .**—Under the name urobilin, Jaffé described a substance which he obtained from dark, febrile urine, and which he regarded as the normal coloring matter of that fluid; subsequently he obtained it from dog's bile and from human bile, from gall-stones and from feces. **Stercobilin**, from the feces, is identical with urobilin.

**Urinary pigments.**—Our knowledge of the nature of the substances to which the normal urinary secretion owes its color is exceedingly unsatisfactory. Jaffé in his discovery of urobilin shed but a transient light upon the question, as that substance exists in but a small percentage of normal urines, although they certainly contain a substance readily convertible into it. Besides the substance convertible into urobilin, and sometimes urobilin itself, human and mammalian urines contain at least one other pigmentary body, **uroxanthin**, or **indigogen**. This substance was formerly considered as identical with **indican**, a glucosid existing in plants of the genus *Isatis*, which, when decomposed, yields, among other substances, indigo-blue. Uroxanthin, however, differs from indican in that the former is not decomposed by boiling with alkalis, and does not yield any glucose-like substance on decomposition; the latter is almost immediately decomposed by boiling alkaline solutions, and, under the influence of acids and of certain ferments, yields, besides indigo-blue, **indiglucin**, a sweet, non-fermentable substance, which reduces Fehling's solution.

Uroxanthin is a normal constituent of human urine, but is much increased in the first stage of cholera, in cases of cancer of the liver, Addison's disease, and intestinal obstruction. It has also been detected in the perspiration.

In examining the color of urine it should be rendered strongly acid with  $HNO_3$  or  $HCl$ , and allowed to stand six hours to liberate combined pigment, and then examined by transmitted light in a beaker three inches in diameter.

**Melanin** is the black pigment of the choroid, melanotic tumors, and skin of the negro; and occurs pathologically in the urine and deposited in the air-passages.

## PART III.

### LABORATORY TECHNIQS.

CHEMISTRY is essentially a science of experiment; and not only is a knowledge of its truths much more rapidly and easily acquired by the student through the actual performance of experiment, than by any amount of reading or attendance upon illustrated lectures; but it is even doubtful whether a thorough knowledge of the facts and theories of the science can be obtained in any other way than by personal observation.

A description of the various manipulations of the general chemical laboratory would fill volumes. A short account of the more prominent of those required in a study of rudimentary chemistry, and in those processes of analysis which are likely to be of service to the physician will, we believe, not be out of place in a work of this nature.

#### GENERAL RULES.

"Cleanliness," said John Wesley, "is next to godliness." The chemist, whatever his supply of godliness, must be thoroughly imbued with the spirit of cleanliness; not so much as regards himself, for he who fears to soil his fingers is not of the material whereof chemists are made, but as regards the vessels and reagents which are his tools. Any substance foreign to the matter under examination and the reagents used, whatever be its nature, is *dirt* to the chemist.

Glass vessels should always be cleaned as soon as possible after using, as foreign substances are much more readily removed then than after they have dried upon the glass. Usually rinsing with clear water, and friction with a probang or bottle brush is sufficient; greasy and resinous substances may be removed with KHO solution; and other adherent deposits usually with HCl or HNO<sub>3</sub>; the alkali or acid being removed by clear water. After washing, the vessels are drained upon a clean surface, and are not to be put away unless *perfectly bright*.

Order and system are imperative, especially if several operations are conducted at the same time. If there be "a place for

everything, and everything in its place," much time will be spared. If a process be of such a nature that it requires a number of vessels, each vessel should be numbered with a small gum label, or by scratching on the glass with a writing diamond, and the notes of the operation should indicate the stage of the process in each vessel.

The habit of taking full and systematic notes of experiments and analyses in a book kept especially for the purpose, is one which the student cannot contract too early. He will be surprised, in looking over and comparing his notes, at the amount of information he will have collected in a short time; much of which, had the memory been trusted to, would have been lost.

### REAGENTS.

The stock of reagents required varies, of course, with the nature of the work to be done; from the small number required in urinary analysis, to the array on the shelves of a fully-appointed analytical laboratory.

The liquid reagents and solutions should always be kept in glass-stoppered bottles (the  $4\frac{1}{2}$   $\frac{2}{3}$  bottles, with labels blown in the glass, serve very well). The solid reagents may be kept in cork-stoppered or, preferably, glass-stoppered bottles. The ordinary glass stoppers should never be laid upon the table, lest they take up particles of foreign matter and contaminate the contents of the bottle; but should be held between the third and little fingers of the right hand.

The reagents required for ordinary urinary analysis are:

Nitric acid,	Ammonium hydrate,
Sulphuric acid,	Cupric sulphate,
Acetic acid,	Fehling's solution,
Potassium hydrate,	Test papers.

Those required for ordinary qualitative analysis are:

Hydrochloric acid,	Potassium ferricyanid,
Nitric acid,	Potassium sulphocyanate,
Sulphuric acid,	Potassium carbonate,
Acetic acid,	Potassium chromate,
Hydrogen sulphid,	Barium chlorid,
Ammonium sulphid,	Calcium sulphate,
Ammonium hydrate,	Magnesium sulphate,
Potassium hydrate,	Cupric sulphate,
Ammonium chlorid,	Argentie nitrate,
Ammonium carbonate,	Mercuric chlorid,
Ammonium oxalate,	Plumbic acetate,
Sodium carbonate,	Ferric chlorid,
Hydro-disodic phosphate,	Platinic chlorid.
Potassium ferrocyanid,	

The chemicals must be C. P. (= chemically pure); and the solutions must be made with distilled  $H_2O$ . It is well to put corre-

sponding numbers on each bottle and stopper to prevent their becoming mixed in cleaning.

### GLASS TUBING.

The tubing used in making all usual connections and apparatus is the soft (German or American) tubing. When the tube is to be strongly heated, Bohemian tubing must be used. The fashioning of tubing of the diameter generally used for gas connections is a simple matter.

Cutting into desired lengths is accomplished by making a scratch with a triangular file at the desired point; holding the tube as shown in Fig. 43; and partly drawing, and partly bending it.

FIG. 43.

Larger glass surfaces may be cut in any required direction, by first making a deep scratch with the file; starting the break by bringing in contact with scratched spot a piece of red-hot glass tubing; and leading the break in the desired direction by applying a heated piece of  $\frac{1}{4}$ -inch iron wire, whose end is filed off square, moved in the desired direction in advance of the crack. Cut ends of tubing should always be rendered smooth by heating them to incipient fusion, or by trimming with a file.

Glass surfaces may be filed without danger of breaking, if the file be moistened with a saturated solution of camphor in oil of turpentine. Holes may also be bored through glass with the sharp edges of a broken rat-tail file, kept moistened with the camphor-turpentine mixture, the hole being started from both surfaces and meeting in the middle.

Bending is done by heating the tube at the desired point in an ordinary gas flame (not a blow-pipe flame), without rotating it, until softened; removing from the flame and bending *toward* that surface which was nearest the orifice of the gas-jet.

FIG. 44.

Closing.—For this and other operations with glass tubing, the glass-blower's flame, obtained with a burner (Fig. 44) which permits of the injection of air into the gas flame, is required. To make a test-tube a piece of tubing of the length of two test-tubes is drawn out at the middle (see below). The small end of each

piece is then heated and the superfluous glass removed by a warm glass rod, which is brought into contact for an instant and then drawn away. The closed end is then heated, during rotation, until soft, and rendered hemispherical by gently blowing into the open end. The open end is then heated, and, while hot, formed into a lip by a circular motion with a hot iron wire.

**Drawing out** consists in heating the tube at the point desired, during rotation, and drawing it apart after removal from the flame.

**Joining.**—Two pieces of tubing of different diameters may be joined end for end if they be of the same kind of glass. The ends of each are closed, heated, and blown out into thin bulbs. The bulb is then broken off, the ends heated, pressed firmly together, and reheated during alternate pressure and drawing apart, and gentle blowing into one end while the other is closed, until an even joint is obtained.

**Stirring-rods** are made by cutting glass rods to the required length and rounding the ends by fusion.

### COLLECTION OF GASES.

Gases are collected over the *pneumatic trough*, by *displacement* of air; or over the *mercurial trough*.

In the pneumatic trough (Fig. 45) gases are collected over

FIG. 45.

water in bell jars filled with that liquid. This method of collection can only be used for insoluble or sparingly soluble gases.

If heat have been used in the generation of the gas, the disengagement tube must be removed from the water *before* the heat is discontinued, to avoid an explosion.

Soluble gases are collected over mercury or by upward or downward displacement of air, according as they are without action on Hg, or heavier or lighter than air.

### SOLUTION.

As the particles of liquids can be brought into closer contact than those of solids, reactions are usually facilitated by bringing the reagents into solution or into fusion.

At a given temperature solution of a solid is more rapid the greater the surface exposed to the solvent, *i.e.*, the greater the degree of subdivision.

Ordinary salts are ground to powder in Wedgwood or glass mortars. Very hard substances are first coarsely powdered in steel mortars, and then finely ground in agate mortars. Soft substances are best subdivided either by hashing, as in the case of muscular tissue, or by forcing through the meshes of a fine sieve, as in the case of white of egg, brain-tissue, etc.

When only certain constituents of the substance are to be dissolved, percolation may be resorted to. The substance to be extracted is packed in a percolator in such a manner that the extracting liquid filters through it slowly.

When the solvent is a volatile liquid—ether, chloroform, carbon disulphid—extraction is best accomplished in an apparatus such as that shown in Fig. 46, in which the liquid is boiled in A; the vapor passing through *a, b*, is liquefied in the condenser and flows back over the substance in B. The extract collects in A.

FIG. 46.

### PRECIPITATION—DECANTATION—FILTRATION— WASHING.

When the conversion of an ingredient of a solution into an insoluble compound, and its separation from the liquid are desired, both the liquid and the reagent should be in clear solution, and

the latter should be added to the former, which has been warmed. The vessel is then set in a warm place until the precipitate has subsided, a few drops of the precipitant are added to the clear liquid, and if no cloudiness be produced the precipitation is complete. Precipitation should be effected in Erlenmeyer flasks (Fig. 47) or in precipitating jars (Fig. 48), that the precipitate may not collect on the sides, and may be readily detached by the wash-bottle.

Precipitates are separated from the liquid in which they have been formed by *decantation* or *filtration*.

**Decantation** consists in allowing the precipitate to subside, and pouring off the supernatant liquid. It should always be employed as a preliminary to filtration, and is sometimes used

FIG. 47.

FIG. 48.

exclusively, when the precipitate is washed by repeatedly pouring on clear water, and decanting it until it no longer contains any solid matter.

In pouring liquid from one vessel to another it should be guided by a glass rod, as shown in Fig. 49; the outer surface of the lip of the pouring vessel having been slightly greased.

**Filtration** is resorted to more frequently than decantation. Filters are made from muslin, paper, asbestos, or glass wool.

Muslin filters are only used for coarse filtration.

Paper filters are the most frequently used. For coarse work the ordinary gray or German white paper is used; but for analytic work a paper which leaves but a small amount of ash is required; the best now in the market is Schleicher & Schüll's Nos. 597 and 589. The filter should be taken of such size that when folded it will be smaller than the funnel in which it is to rest. It is folded across one diameter, and again over the radius at right angles to the first diameter; one of the four layers of paper, then seen at the circular portion of the filter, is separated from the other three, in such a way as to form a cone. The filter so formed is brought into the funnel, and, while held in position by

a finger-nail over one of the folds, is wetted with water from the wash-bottle. After the paper has been brought in contact with the funnel by a glass rod, the liquid to be filtered is introduced, care being had not to overflow the filter, and to allow any supernatant liquid in the precipitating jar to pass through, before bringing the precipitate itself upon the filter. Funnels used for filtering should have an angle of  $60^\circ$ , and a long stem, the point of which is ground off at an acute angle.

Asbestos and glass wool plugs loosely introduced into the stem

FIG. 49.

of a funnel, are used in filtering such liquids as would destroy paper.

For filtrations which take place slowly the *filter-pump* is now extensively used. It is simply an appliance for exhausting the air in the stem of the funnel, and thus taking advantage of atmospheric pressure. A simple and effective form of pump is that shown in Fig. 50, in which the water (under 10 feet or more of pressure) enters at *a* and aspirates the air from *b* through *c*. When the pump is used a small cone of platinum foil must be placed at the apex of the funnel to support the point of the filter, which would otherwise be ruptured.

When the precipitate has been collected upon the filter, it must be *washed* until free from extraneous matter. This is effected by blowing into the tube *a* of the wash-bottle (Fig. 51), while the end

of the tube *b* is held so as to deliver a *gentle* stream into the filter; care being had that the precipitate is not lost by spurting, overflowing, or *creeping* up the sides of the funnel. The completeness of the washing is *not to be guessed at*, but is to be judged by adding reagents, suitable to the case, to portions of the filtrate until they fail to cause a cloudiness.

FIG. 50.

FIG. 51.

If the precipitate adhere to walls of the vessel in which it has been formed, it may usually be detached by rubbing with a brush, formed by slipping a short section of rubber tube over the end of a stirring-rod, or, if this fail, the precipitate must be re-dissolved and reprecipitated by an appropriate solvent and precipitant.

### EVAPORATION—DRYING—IGNITION.

**Evaporations** are usually conducted on the sand- or water-bath. The sand-bath is simply a flat, iron vessel, filled with sand and heated. By its use the heat is more evenly distributed than with the naked flame.

The water-bath, usually of the form shown at *a* Fig. 52, is used where the temperature is to be kept below 100° (212° F.). It should *always* be used in evaporating liquids containing organic matter, and care should be had that it does not become dry.

In cases where it is desired to boil an aqueous liquid in a glass or porcelain vessel; this is supported on a piece of wire gauze and

a Bunsen burner or spirit lamp brought under it (Fig. 53). A piece of sheet-iron may be substituted for the wire gauze, with

FIG. 52.

FIG. 53.

flat-bottomed vessels. The outside of the heated vessel must be *dry*.

In heating liquids in test-tubes, *the mouth of the tube must be held away from the person*. It is best held by a piece of thick

FIG. 54.

FIG. 55.

paper bent around the upper end of the tube (Fig. 54). The tube should be heated near, not at its bottom.

In no case should flame, or the sand of the sand-bath, come in contact with a glass vessel above the level of the liquid within.

**Drying** is always necessary as a preliminary to weighing, whether the substance is hygroscopic or not. It is usually effected in water-ovens (Fig. 55), if a temperature of 100° (212° F.) be sufficient; or in air-ovens, somewhat similarly constructed, if a higher temperature be desired. As a substance can never be accurately weighed while it is warm, it is removed from the oven and placed in the desiccator (Fig. 56), over  $\text{H}_2\text{SO}_4$  or  $\text{CaCl}_2$ , until it has cooled.

In cases where the substance would be injured by elevation of temperature, it is dried by allowing it to remain in the desiccator until it ceases to lose weight.

**Ignition** has for its object the removal of organic matter by

FIG. 56.

FIG. 57.

burning, and is conducted in platinum or porcelain crucibles. If a filter and precipitate are to be ignited, they are first well dried; as much as possible of the precipitate is detached and brought into the crucible, placed upon a sheet of white paper; the filter, with adherent precipitate, is then rolled into a thin cone, around which a piece of platinum wire is wound; by means of the platinum wire the filter is held in the flame and burnt; the remains of the filter are then added to the contents of the crucible, which is supported in the position shown in Fig. 57, in which it is heated, at first moderately, and the heat gradually increased to bright redness, at which it is maintained until no carbon remains. Before weighing, the crucible is to be cooled in the desiccator.

In igniting it must not be forgotten that mineral substances

may be modified or lost. Carbon at high temperature deoxidizes easily reducible substances; alkaline chlorids are partly volatilized; mineral bases combined with organic acids are converted into carbonates. In every instance only that amount of heat which is required is to be applied. In some cases it is well to accelerate the oxidation by the addition of ammonium nitrate.

### WEIGHING.

The balance (Fig. 58) should always be kept in a glass case, containing a vessel with  $\text{CaCl}_2$ , and in a situation protected from the

FIG. 58.

fumes of the laboratory. The weights should be kept in a box by or in the balance case, which is to be closed when not in use.

In weighing observe the following rules:

(1.) See that the balance is in adjustment before using, especially if more than one person use it. (2.) Always put the substance to be weighed in the same pan, usually the left-hand one, and the weights in the other. (3.) Never bring any chemical in contact with the pans, but have a pair of large watch-glasses of

equal weight, one in either pan. Pieces of paper will *not* serve the purpose. (4.) Always put the balance out of action before adding anything to, or taking anything from, either pan. (5.) Never weigh anything warm. (6.) In weighing a substance which has been dried, do not consider the weight correct until two successive weighings, with an intervening drying of a half-hour, give identical results. (7.) In adding the weights, do so in regular order from above downward. (8.) In counting the

FIG. 59.

weights, reckon the amount first by the empty holes in the box, and then tally in replacing the weights. (9.) Substances liable to absorb moisture from the air are to be weighed in closed vessels. Thus, when a filter and its adherent precipitate are to be weighed together, they must be placed between the two watch-glasses (Fig. 59) as soon as taken from the drying-oven; one of the watch-glasses being used to support the filter in the oven.

### MEASURING—VOLUMETRIC ANALYSIS.

The principle upon which volumetric analysis is based is that by determining the volume of a solution of known strength, required to accurately neutralize another solution of unknown strength, the amount of active substance in the latter may be calculated.

If, for example, we have a solution of silver nitrate which contains 170 grams to the litre, and we find that 12 c.c. of this solution precipitate all the chlorine from 10 c.c. of a solution of NaCl, it follows that the NaCl solution contains 70.20 grams of that substance per litre, because:

and therefore each c.c. of the AgNO<sub>3</sub> solution will accurately precipitate 0.0585 gram NaCl; but as it has required 12 c.c. of the AgNO<sub>3</sub> solution to neutralize 10 c.c. of the NaCl solution, the lat-

ter contains  $0.0585 \times 12 = 0.702$  gramm. NaCl, or 1,000 contain  $0.702 \times 100 = 70.20$  grms. NaCl.

It is obvious, therefore, that the value of volumetric methods depends, among other things, greatly upon the accuracy of the standard solutions, as the solutions of known strength are called, and upon the accuracy of the measurements of volume.

A standard solution containing in a litre of liquid a number of grams of the active substance, equal to its molecular weight, is a normal solution; one containing  $\frac{1}{10}$  that amount is a decinormal solution.

An indicator is a substance which, by some characteristic reaction (*end reaction*), which will occur only when the substance to be determined has been completely removed, indicates the point when a proper volume of the standard solution has been added.

The apparatus required for volumetric analysis consists of:

(1.) A litre-flask (Fig. 60); a flask of such size that, when filled to the mark on the neck, at the temperature for which it has been graduated, it contains exactly 1,000 c.c. of water.

(2.) A burette, which is a glass tube graduated into cubic centimetres, and having a stopcock or pinch-cock at its lower extremity.

(3.) A series of pipettes (Fig. 61), which are glass tubes, having bulbs blown upon them of such size that when they are filled to a mark on the tube above the bulb, they contain a given number of cubic centimetres.

(4.) Small beakers; stirring-rods; bottles for standard solutions.

In making a standard solution the object to be attained is to have a solution, one litre of which shall contain a known quantity of the active material. If then in the formula for the normal solution of silver nitrate:

Silver nitrate.....	170 grams.
Distilled water.....	1,000 c.c.

we weigh out the  $\text{AgNO}_3$  on the one hand, and measure the  $\text{H}_2\text{O}$  on the other, and mix the two, we will have, not what is desired, a solution containing 170 grms.  $\text{AgNO}_3$  in 1,000 c.c., but a solution of 170 grms.  $\text{AgNO}_3$  in  $1,000 + x$  c.c. of liquid, in which  $x$  = the volume occupied by the  $\text{AgNO}_3$ . Therefore, in making

FIG. 60.

FIG. 61.

standard solutions, weigh out the active substances; introduce them into the litre-flask; and then fill that to the mark with  $H_2O$ .

FIG. 62.

Too much caution cannot be used in having pure chemicals and making accurate weighings in preparing volumetric solutions; indeed, the great disadvantage of the use of these methods by physicians is that the solutions which they use are carelessly prepared and, consequently, the time which they spend in obtaining inaccurate, but seemingly accurate, results is worse than thrown away.

To use a volumetric solution it is poured into the burette, whose stopcock has been closed, until above the 0 mark; the stopcock is then slightly opened so as to expel *all* air from the delivery tube. The float (Fig. 62) is now introduced from above, and touched with a glass rod to free it from adhering air-bubbles; and the solution allowed to flow out from below until the mark on the float is opposite the 0 of the burette. All is now ready for use; a given quantity of the solution to be analyzed is measured into a pipette and placed in a beaker, a few drops of the indicator solution are added, and the standard solution allowed to flow in until the end reaction is reached. The reading of the burette is then taken and the calculation made.

# **SCHEME FOR DETERMINING THE COMPOSITION OF URINARY CALCULI.**

1. Heat a portion on platinum foil :
  - a. It is entirely volatile ..... 2
  - b. A residue remains. .... 5
2. Moisten a portion with  $\text{HNO}_3$  ; evaporate to dryness at low heat ; add  $\text{NH}_4\text{HO}$  :
  - a. A red color is produced. .... 3
  - b. No red color is produced. .... 4
3. Treat a portion with  $\text{KHO}$ , without heating :
  - a. An ammoniacal odor is observed. *Ammonium urate.*
  - b. No ammoniacal odor. .... *Uric acid.*
4. a. The  $\text{HNO}_3$  solution becomes yellow when evaporated ; the yellow residue becomes reddish-yellow on addition of  $\text{KHO}$ , and, on heating with  $\text{KHO}$ , violet-red. .... *Xanthin.*  
 b. The  $\text{HNO}_3$  solution becomes dark brown on evaporation. .... *Cystin.*
5. Moisten a portion with  $\text{HNO}_3$  ; evaporate to dryness at low heat ; add  $\text{NH}_4\text{HO}$  :
  - a. A red color is produced. .... 6
  - b. No red color is produced. .... 9
6. Heat before the blow-pipe on platinum foil :
  - a. Fuses ..... 7
  - b. Does not fuse. .... 8
7. Bring into blue flame on platinum wire :
  - a. Colors flame yellow. .... *Sodium urate.*
  - b. Colors flame violet. .... *Potassium urate.*
8. The residue from 6 :
  - a. Dissolves in dil.  $\text{HCl}$  with effervescence ; the solution forms a white ppt. with ammonium oxalate. .... *Calcium urate.*
  - b. Dissolves with slight effervescence in dil.  $\text{H}_2\text{SO}_4$  ; the solution, neutralized with  $\text{NH}_4\text{HO}$ , gives a white ppt. with  $\text{HNa}_2\text{PO}_4$ . .... *Magnesium urate.*
9. Heat before the blow-pipe on platinum foil :
  - a. It fuses ..... *Ammonio-magnesian phosphate.*
  - b. It does not fuse. .... 10
10. The residue from 9, when moistened with  $\text{H}_2\text{O}$ , is :
  - a. Alkaline. .... 11
  - b. Not alkaline. .... *Tricalcic phosphate.*
11. The original substance dissolves in  $\text{HCl}$  :
  - a. With effervescence. .... *Calcium carbonate.*
  - b. Without effervescence. .... *Calcium oxalate.*

NOTE.—A fresh portion of the powdered calculus is to be taken for each operation except where otherwise stated.

## APPENDIX.

## APPENDIX A.

### ORTHOGRAPHY AND PRONUNCIATION OF CHEMICAL TERMS.

At its Cleveland meeting in 1888 the Chemical Section of the American Association for the Advancement of Science appointed a committee, consisting of Professors Norton, Hart, Bolton, and Howe, to formulate and submit to the Section a body of rules to govern the spelling and pronunciation of chemical terms, which should represent the consensus of opinion of American chemists. This committee reported at the Toronto meeting in 1889. As this report represents the most recent views upon this subject, it is here reprinted in full :

#### GENERAL PRINCIPLES OF PRONUNCIATION.

1. The pronunciation should be as much in accord with the analogy of the English language as possible, yet continental pronunciation should be approached, inasmuch as it is used by a large proportion of the world's chemists, and by a continually increasing number of American chemists.

2. Present usage should be retained as far as possible.

3. Derivatives should keep as far as possible the accent and pronunciation of the root word, in order to make the original sense as clear as possible. This is subordinate to Rule 1.

4. Distinctly chemical compound words should retain the accent and pronunciation of each portion.

5. Similarly sounding endings for dissimilar compounds should be avoided, hence -*in*, -*id*, -*ite*, -*âte*.

6. Utility often determines usage even when contrary to analogy.

#### PREFIXES.

GENERAL RULE.—All prefixes in strictly chemical words should be considered as parts of compound words, and hence should retain their own pronunciation, unchanged.

mō'no-	nī'tro- or nī'tro- (Hart:	anh'y'dro-
dī-	nī'tro-)	arsē'nio-
bī-	nītrō'so- or nītrō'so-	xā'ntho-
trī-	ā'zo-	ī'so- (Howe : ī'so-)
tē'tra-, etc.	dīā'zo-	mē'thyl-
ā'cēto-	ā'zo-ā'mido	ē'thyl-
*ā'mīdo- (Bolton :	h'y'dro-	prō'pyl-, etc.
amī'do-)		

## NON-METALS, ETC.

h'y'drogen	gl'y'cogen	sū'lphur
ō'xygen	āmī'dogen	phō'sphorus
nī'trogen	*chlō'rīn	ca'rbon
hā'logen	*brō'mīn	bō'ron
c'yā'nogen	*ī'odīn	sī'licon
dī'cya'nogen	*flū'orīn	†arsē'nicum
pā'racya'nogen		

## METALS.

Usage has determined the pronunciation except in a few instances.

ā'ntimony	ma'nagense (ez as in	ku'pfērni'ckel (koop)
bī'smuth (biz-)	breeze)	sī'lver
cō'balt	mē'reury	tū'ngsten
co'pper	nī'ckel	zinc
ī'ron		

Words in *-ium* have antepenultimate accent, and the vowel of this syllable is short if *i* or *y*, or if before two consonants, but long otherwise.

*alū'minum (Bolton	īr'dium	strō'ntium (shium)
& Howe : alumī'n-	lī'thium	tellū'rium
ium)	magnē'sium (zhium)	te'rbiūm
ammō'nium	nīō'biūm	thā'llium
dīē'thylammō'nium	ō'smīum	thō'rium
bā'rium (Bolton: bā'r-	pallā'dium	†tītā'nium
ium)	phosphō'nium	ūrā'nium
beryl'lum	dīē'thylphosphō'nium	vānā'dium
cad'mium	potā'ssium	ytte'rbiūm

Fāte, fāt, fār, mēte, mēt, pine, pīn, marīne, nōte, nōt, mōve, tūbe, tūb, rūle, m'y, ŷ = Y.

Primary accent ; " secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

caē'sium	rhō'dium	ŷ'ttrium
ca'leium	ruthē'nium	zircō'nium
cē'rium	samā'rium	lā'nthanum
chrō'mium	sca'ndium	†mōlŷ'bdenum
†dīdŷ'mium	sēlē'nium	plā'tinum
e'rbium	sō'dium	tā'ntalum
ŷ'ndium		

TERMINATIONS IN -IC.

Accent penultimate.

Penultimate vowel in polysyllabic words short, except (1) *u* when not before two consonants; and (2) when penultimate syllable ends in a vowel: in dissyllables long, except before two consonants.

alūmŷ'nic	†nŷ'ekelic (ni'ck'lie)	borā'cie
ammō'nic	platŷ'nic	bō'rie
argē'ntic	plū'mbic	brō'mic
bā'rie	strō'ntic	carbō'nic
bismū'thic	tītā'nic	dīthīō'nic
coba'ltic (a as in ball)	ūrā'nic	fē''rrocŷā'nic
mangā'nic		hydrīō'die
mercū'rie	arsē'nic	hy''drochlō'rie
īō'die	benzō'ic	phthā'lie (tā'lie)
mē''tantimō'nic	butŷ'rie	pŷ'erie
mē''taphosphō'rie	caodŷ'lie	prū'ssie
mē'tastā'mic	camphō'rie	†racē'mic or racē'mic
mōlŷ'bdie	carbā'mic	rosē'llie
phosphō'rie	carbō'lie	sacehā'rie
py''rophosphō'rie	carbō'nie	salicy'lie
sēlē'nie	†chlō''racētic or chlō''	sebā'cie
silŷ'cie	racē'tic	sūbē'rie
sū''lphocŷā'nic	chrŷsophā'nie	tārtā'rie
tellū'rie	cinnā'mic	†valē'rie or valē'rie
abiē'tic	cŷ'tric	succē'nie
†acē'tic or acē'tic	cyanū'rie	
abietŷ'nie	dīālū'rie	alē'mbic
absŷnthic	fūmā'rie	allotrō'pie
ācē'rie	glycō'lie	aromā'tic
ācētō'nie	hippū'rie	atō'mic

Fāte, fāt, fār, mēte, mēt, pīne, pīn, marīne, nōte, nōt, mōve, tūbe, tūb, rūle, mŷ, ŷ=ŷ.

Primary accent; secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

áčěť'lic	hŷpogaě'ic	bā'sic
acon'ťic	ī'sobutŷ'ric	elě''etrolŷ'ťic
aerŷ'lic	mā'lic	isomě'ric
adl'pic	malō'nic	mō''nobā'sic
alcohō'lic	mellŷ'ťic	mō''nohŷ'dric
alizā'ric	methŷ'lic	polymě'ric
allŷ'lic	mū'cie	tětratō'mic
amygdā'lic	myrō'nic	tribā'sic
amŷ'lic	olě'ic	

## TERMINATIONS IN -OUS.

Words in *-ous*, following the general rule of the language, take antepenultimate accent, except when two consonants follow the penultimate vowel, in which case the accent is thrown forward.

(A clear distinction is thus made in accent as well as in termination between words in *-ic* and *-ous*.)

ťacě'tous (exception through usage)	sělě'nious	plā'tinous
arsē'nious	sŷlphūrous	tŷtanous
chlō'rous	tě'llūrous	alliā'ceous
hy''drosŷlphūrous	bŷsmŷthous	alumenŷ'ferous
hy''pochlō'rous	chrō'mous	amŷlā'ceous
hy''ponŷtrous	cō'baltous	aurŷ'ferous
hy''pophō'sphōrous	mānganous	gā'seous (gazeous)
hy''posŷlphūrous	mě'reūrous	gela'tinous
phō'sphōrous	nŷckelous	pyrolŷgneous

## TERMINATIONS IN -ATE.

Antepenultimate accent (occasionally thrown back).

ā'biětāte	al'zarāte	cŷ'ānāte
ā'cerāte	ammō'niāte	fŷlmināte
ā'cětāte	amŷ'gdalāte	glŷ'cöllāte
ā'cetonāte	ā'mylāte	vā'nadāte
ā'dipāte	antimō'niāte	ťťŷtrāte
ā'lcoholāte	ā'senāte	

## TERMINATIONS IN -ITE.

Accent analogous to *-ate* terminations.

ā'cetite	ā'senite	mā'nnite
ā'ntimonite	hy''pophō'sphite	

Fāte, fāt, fār, mēte, mět, pīne, pīn, marīne, nōte, nőt, mōve, tūbe, tŷb, rūle, mŷ, ŷ=ŷ.

Primary accent : secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

TERMINATIONS IN -IDE AND -ID.

\* Drop final *e* in every case, and pronounce *-id* (see Note 1). Antepenultimate accent.

ă'cētă'nīd	cyă'melīd	ă'lkală'mīd
hŷ'drīd	glū'cosīd	bě'nzylă'mīd
anhŷ'drīd	hy''drosŭlphīd	că'rbă''mīd
ă'nīd	ō'xīd	cyă'nă''mīd
brō'mīd	hŷdrō'xīd	dī'ă'cētă'mīd
chlō'rīd	murē'xīd	dīcyă'nă''mīd
flū'orīd	ō'xylō'rīd	lă'etă'mīd
ī'odīd	ă'mīd	ō'xă'mīd
cy'ănīd	ă'cētă'mīd	

TERMINATIONS IN -ANE.

Hydrocarbons belonging to the *-ane*, *-ene*, and *-ine* groups of Hofmann take long vowel.

mē'thāne	hē'ptāne	ī'sobŭ'tāne
ě'thāne	ō'ctāne	ī''sopě'ntāne
hē'xāne		

TERMINATIONS IN -ENE.

Antepenultimate accent. Some dissyllables, as benzene, have no distinct accent.

ă'cēnă'phthēne	ăcě'tylēne	ă'mylēne
ă'cētnă'phthylēne	ă'llylēne	ťă'nthracēne
ă'sphāltēne	dībrōmbēnzēne	oēnanthŷ'lidēne
ă''zobě'nzēne	ě'thidēne	pě'ntylēne
bēnzēne	ě'thylēne	phenă'nthrēne
bě'nzylēne	hě'ptylēne	terabě'nthēne
bŭ'tylēne.	ī''sobŭ'tylēne	tō'lūēne
caprŷ'lidēne	ī''sohě'ptylēne	valě'rylēne
cētēne	mesī'tylēne	xŷ'lēne
crotō'nylēne	mě''taxy'lēne	
decě'nylēne	mě'thylēne	glŭ'tēn
dīă'mylēne	nă'phthalēne	*albŭ'men

TERMINATIONS IN -INE.

Doubly unsaturated compounds in *-ine* take the normal pronunciation *-ine*.

ě'thīne	prō'pīne
---------	----------

Fāte, fāt, fār, mēte, mēt, pīne, pīn, marine, nōte, nōt, mōve, tūbe, tŭb, rūle, mŷ, ŷ=ī.

Primary accent : ' secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

## TERMINATIONS IN -IN.

\* All chemical compounds now ending in *-in* and *-ine* (except doubly unsaturated compounds, considered above) should end in *-in*, and this syllable should be pronounced *-in* (see Note 2).

The accent is antepenultimate, except when the penultimate vowel is followed by two consonants, in which case the accent is penultimate.

chlō'rīn	bě'nzīn	quī'nidīn
brō'mīn	brū'cīn	quī'nīn
ī'ōdīn	chō'līn	rōsā'nīlīn
flū'ōrīn	chrý'soidīn (oi as in soil)	stry'chnīn
ā'mīn		tolū'idīn
mě'thylā'mīn	cinchō'nicīn	vā'sēlīn
ě'thylā'mīn	cī'nehōnīn	ā'bīētīn
ā''cēdiā'mīn	cō'nīn	ābsī'nthīn
ā'cetonā'mīn	crēā'tīnīn	ā'cētīn
phō'sphīn	crē'atīn	alī'zarīn
ā'rsīn	cū'rarīn	alloxā'ntīn
ā'conīn	guā'nidīn (gwā)	ā'llylīn
acō'nitīn	guā'nīn (gwā)	amý'gdalīn
ā'mmelīn	hý'drazīn	ā'mylīn
ā''nthrapu'rpu'rīn	hyoseý'amīn	au'rīn
ā'sbolīn	mo'rphīn	coní'ferīn
ā'nīlīn	ō'lēfīn	cū'marīn
aspā'ragīn	quī'nicīn	dē'xtrīn
diēhlōrhý'drīn	mý'osīn	*thē'īn (tē'īn) (Hart : word should be dropped)
diē'thylīn	nā'reotīn	thē'matīn
dīstē'arīn	neū'rīn	†ī'ndigotīn
emū'lsīn	ný'cotīn	ī'nulīn
fī'brīn	pā'lmitīn	ī'satīn
flū'orē'scīn	pāpā'verīn	leū'cīn
gē'latīn	pē'psīn	mō''nostē'arīn
glō'būlīn	pīpē'ridīn	ā'tropīn
glī'adīn	pu'rpu'rīn	sy'ntōnīn
glū'tīn	reso'reīn	tā'nnīn
gly'cerīn (gly'cerōl preferred)	sā'licīn	*vā'nīlīn
†hē'moglō'bīn	sā'reīn	
	stō'arīn	

Fāte, fāt, fār, mēte, mēt, pīne, pīn, marīne, nōte, nōt, mōve, tūbe, tūb, rūle, mý, ý = I.

' Primary accent ; '' secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

(In following nine words, penultimate accent ob- served.)	cā ffeĭn	allā ntōin
thē'baĭn	cō'deĭn	†bēnzōĭn
†cō'caĭn	cā seĭn	
acrō'leĭn	flūorē'sceĭn	ā'lkaline
	nā'rceĭn	cry'stallĭn or cry'stal- line.
	cōniĭn	

TERMINATIONS IN -ONE AND -ON.

*albū'mĭnōne	ā'cētōne	hŷ''drēcā'rbōn
ā'nthraqūnōne		collō'diōn
quĭnōne	bō'rōn	sĭ'licōn
kētōne	cā'rbōn	

TERMINATIONS IN -AL, -IL, -OL, -YL, -YDE, ETC.

ā'cetāl	chlō'rāl	ā'cētonī'trĭl
bē'nzāl	nī'trĭl	

-ol, final *e* dropped : *ōl*, with two exceptions from usage.

ā'leohōl	crē'sōl	†nā'phthōl
ā'nēthōl	glŷ'cerōl	*phē'nōl
ā'rgōl	†glŷ'cōl	*thŷ'mōl (tī)
be'nzōl (undesirable; should be dropped)	ŷ'ndōl	

-yl, antepenultimate accent.

ācē'tonŷl	ā'mŷl	bū'tŷl
†ācētŷl	bŷ'smūthŷl	cā'codŷl
ālŷl	bō''rē'thŷl	cā'rbonŷl
†cārbō'xŷl	dīphē'nŷl	lā'etŷl
cē'rotŷl	dīprō'pŷl	mē'thŷl
cē'tŷl	fo'rmŷl	†nītrō'xŷl
chrō'mŷl	hē'ptŷl	nī'trŷl
dīā'lyl	†hydrō'xŷl	ō'etŷl
dīā'mŷl	ī'sobū'tŷl	†phē'nŷl
dīmē'thŷl	ī'soprō'pŷl	prō'pēnŷl

-yde, antepenultimate accent.

†ā'ldehŷde	bē'nzā'ldehŷde	pā'rā'ldehŷde
ā'cētā'ldehŷde	mē'tā'ldehŷde	

Fāte, fāt, fār, mēte, mēt, plne, plu, marĭne, nōte, nōt, mōve, tūbe, tūb, rūle, mŷ, ŷ = ĭ.

Primary accent : secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

## -METER.

†Words ending in the termination *-meter* take the normal antepenultimate accent (from usage) ; except that the words of this class used in the metric system are considered as compound words, and each portion retains its own accent.

ăcētī'meter	mīcrō'meter (instru-	dē'kamē'ter
ăcētō'meter	ment)	dě'cimē'ter
ăcīdī'meter	urēō'meter	hē'ctomē'ter
alcoholō'meter	urinō'meter	kŷ'lomē'ter
alkalī'meter		mŷ'riamē'ter
bārō meter	mī'llimē'ter	mī'crōmē'ter (meas-
eudiō'meter	cē'ntimē'ter	ure)

## MISCELLANEOUS.

brō'moform	ăcētī'metry	bī'vā'lent
chlō'roform	ăcīdī'metry	trī'vā'lent
iō'doform	alcoholō'metry	†qua'drivā'lent
ă'mylōse	alkalī'metry [in boil]	qui'nquivā'lent
cē'llulōse	†stoichiō'metry (oi as	atom'city
dē'xtrōse	alcoholomē'tric	basī'city
glū'cōse	baromē'tric	mō'nad
lă'ctōse	acētificā'tion	tē'trad
†lē'vūlōse	cupellā'tion	†ā'llotrōpy
ma'ltōse (a as in ball)	distillā'tion	†ā'llotrōpism
sū'crōse	ebullī'tion	†ī'somerism
sy'nāptose	fermentā'tion	†pōlymerism
ă'lkaloid	lixiviā'tion	anā'lysis
ă'mylōid	†tītīrā'tion	atmō'lysis
cō'lloid	vā'lence	dīā'lysis
er'ystalloid	qua'ntivā'lence	electrō'lysis
*albū'minoid	mō'novā'lent	acē'tify
acī'dify	†grām(so derivatives)	†bāry'ta
ă'erate	†līter	bō'rax
ăē'riform	†tīter (to be avoided)	cā'ramel
†alloy' (noun)	†tītrāte	lŷ'tharge
†alloy' (verb)	†tītrā'tion	†olē'flant
amă'lgam	aumō'nia	saltpē'ter
amă'lgamā'tor	ammō'niac	ve'rdigris

Fāte, fāt, fār, mōte, mēt, pīne, pīn, marīne, nōte, nōt, mōve, tūbe, tūb, rūle, mŷ, ŷ = Ÿ.

Primary accent ; " secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

*apparâ'tus	ammōnī'ācāl	ācē'cular
*apparā'tus (plural)	*āntimonetted	ālechēmist
†a'ssay (noun)	*ā'rsenetted	ā'node
†assay' (verb)	cā'rbutted	āqua fo'r'tis
assay'er	te llūretted	āqua rē'gia (re-gi-a)
*cōncentrated	sūlphūretted	cēntigrade
dēflagrating	phōsphoretted	crystallōgraphy
dilū'te	ā'dipocere	fū'marole
*mō'leculē	ā'lkali	gāngue
*mōlē'cular	ā'kanet	mē'tallu'rgy
fe'rment (noun)	†allō'xan	*nō'mēncēlā'ture
fermē'nt (verb)	āntichlor	*ra'dical
na'scent	†asbe'stos	epeiss (spīce)
†mē'ter	ā'sphālt	tū'bulature

Fāte, fāt, fār, mēte, mēt, pīne, pīn, marine, nōte, nōt, mōve  
tūbe, tūb, rūle, mŷ, ȳ = i.

Primary accent : " secondary accent. N. B.—The accent follows the vowel of the syllable upon which the stress falls, but does not indicate the division of the word into syllables.

NOTE 1. *ād*.—This pronunciation distinguishes clearly between *-ād* and *-ite*. In German it is difficult and often impossible to distinguish between *-id* and *-it*, and in English a confusion often arises between chlorite and chloride, sulphite and sulphide, etc.

See also the following note.

NOTE 2. *ām*.—The final *e* in these words should be dropped as of no important significance.

I. The suggestion of Watts and others to indicate basic substances by *-ine* and all others (or neutral substances) by *-in* seems unwise. It makes a difference in spelling, with little or no corresponding difference in pronunciation on the part of most chemists—a useless and undesirable complication. It demands a very extensive knowledge of the constitution of a great number of compounds with these terminations. It has been partially adopted by many chemists but not consistently by most, and by many it has never been recognized.

II. All continental languages use the pronunciation *-in*, and this is the case with not a few words in English, as benzine, marine, while the American public have instinctively taken up this pronunciation in "Pearline, Soapine," etc. In general, however, it seems too foreign to English usage to be adopted by a majority of American chemists.

*-ine* is awkward and would be very foreign to English usage in many words, as chlorīne, morphīne, nicotīne, brucīne, etc., etc.

The pronunciation *-in* is already common in many of these words, as the halogens, anilīn, hematin, pepsin, tannin, etc., and at the same time presents a near approach to the continental *in*, into which it may easily be strengthened if preferred.

The above note applies equally to the termination *-id*.

# APPENDIX B.—TABLES.

## TABLE I.—SOLUBILITIES.

FRESENIUS.

W or w = soluble in H<sub>2</sub>O. A or a = insoluble in H<sub>2</sub>O; soluble in HCl, HNO<sub>3</sub>, or aqua regia. I or i = insoluble in H<sub>2</sub>O and acids. W-A = sparingly soluble in H<sub>2</sub>O, but soluble in acids. W-I = sparingly soluble in H<sub>2</sub>O and acids. A-I = insoluble in H<sub>2</sub>O, sparingly soluble in acids. Capitals indicate common substances.

TABLE I.—SOLUBILITIES.—Continued.

## FRESSENIUS.

W or w = soluble in  $H_2O$ . A or a = insoluble in  $H_2O$ ; soluble in  $HCl$ ,  $HNO_3$ , or aqua regia. I or i = insoluble in  $H_2O$  and acids. W-A = sparingly soluble in  $H_2O$ , but soluble in acids. W-I = sparingly soluble in  $H_2O$  and acids. A-I = insoluble in  $H_2O$ , sparingly soluble in acids. Capitals indicate common substances.
